1829.
PREFACE.

The present is a reprint of the former volume, which bore for title, "The Veterinary Surgeon," with the necessary improvements, and such additions as the lapse of nearly two years of rigid devotion to the subject would produce, as naturally as the grass grows. But a slight alteration being deemed proper in a commercial point of view, the reader will discover the reasons in a note, which was appended to the Preface to that Original Edition*; as he will also in another circumstance of an adverse nature, now pacified, and therefore of no further consequence to the public, unless, indeed, to the curious part of it, who will find, on perusing the last leaf of the Grooms' Oracle, that my coadjunctor and self experienced some unfairness in a certain quarter, now no more!

Whatever person would consult these pages with the requisite profit, should previously read the first book with care; for in it he will find laid down the

* I then said, at page xiv. "the volume has been a long time at press, and in October last year was fully announced by advertisement. The author could not therefore satisfactorily account why his title was adopted by another in the month of April of the present year," (1827.) The entire failure of that attempt, however, forms one more of those painful monitions people derive from experience.
principles upon which all the subsequent details are founded, how the process of nature is carried on in health, and the cure is to be effected in every species of derangement, by restoring the due performance of those functions. Indeed, he should study it hard, if he would become proficient in "the Art of Farriery," and not rely implicitly upon other people's prescriptions for the cure of any alleged disorder, which have been composed for the most part without any such preparation. From this neglect, also, symptoms of one disorder are confounded with those of another, when the proposed remedies cannot possibly effect the cure; and the anomalies and changes that occur in the course of every attack are not watched and noted with sufficient care.

If he is embued with the proper thirst after knowledge, be his station in life about the horse what it may, the student had best to comply with the advice strenuously urged at the very outset, to examine the internal parts of dead horses, as often as opportunity presents itself, which in the neighbourhood of large towns and hunts is frequent enough. For this is the manner in which I was myself mainly instructed; as well as by noting down whatever then appears worthy of observation, connected with the previous disease of the deceased subject. To pave the way for more erudite studies, I have in this edition devoted a dozen pages of Introduction to the Study of Horse Anatomy; quite elementary, and very slight, it is most true, but I trust
they will be read without occasioning trouble, if not with interest.

Such was my manner of proceeding from early youth, with daily practice of Farriery going on, for several years, until at length, in 1803, I became an author, or rather a translator of La Fosse's *Manuel d'Hippiatrique*. This was done at the request of Mr. Badcock, of Paternoster Row, with whom I since then entered into close intimacy, as my late father had already done. But I shall pass no compliments with a man who uses none himself, nor acknowledge the helps I have derived from his advice and his pen, further than appeared in the Preface to my first edition, at page ix.

At that time we belonged to the old school, or rather no school; but notwithstanding this, my revered parent sustained a high character for successful practice, and I filled up the chasm by tolerably severe study, and gave the result occasionally to the sporting periodicals, as *Weekly Dispatch*, *Sporting Magazines*, *Annals of Sporting*, and other works of the like tendency. Of my father's proficiency something is already before the public; and my own opinion of it may be seen in the Grooms' Oracle, page 105, edit. first. And with such examples before us as those of C. Celsus, of Sir John Sinclair, and the small means originally brought to the task by Hunter, let no one hereafter, with the requisite love for the study, shrink from investigating the subject we consent to call The Curative Art.

The reputation of our name induced the book-
seller just named to ask my father’s opinion, and mine among others, of a certain manuscript he held in his hand, which upon inspection turned out to be a treatise on the rationale of horse-medicine, with very plain directions for ascertaining the true symptoms of diseases before attempting to apply any remedy, however estimable. As the expositions of the writer agreed mainly with our own ideas, it was impossible to withhold approbation. Finally, Mr. Badcock also consulted with W. S. Rickword, of Moor-lane, and other veterinary surgeons of the college, and resolved upon the spirited publication of his new purchase; notwithstanding he had received the uncheering disapproval of Bracy Clark, of Smithfield, who gave for answer that “no one could learn the treatment of horses’ diseases from printed books.” Yet has Bracy Clark since then printed many books. The great success of the publication alluded to, which was James White’s “Compendium of the Veterinary Art,” justified our opinion of its merits, and gratified my vanity at the early share I took in its promulgation, and the revision of many passages with a view to simplifying the terms (in particular); in which commendable quality, by the way, Mr. White is not deficient, though, in other respects, a lapse or two which have since fallen out, come under notice in the course of the following pages. No man can be perfect: how few among us know every thing that pertains to themselves *

* The edition of White’s Compendium I have used is the 12th,
Even now, after all my care and revision, I am not certain but I may be found similarly tripping—to have expressed myself obscurely, when I fancied my language most completely understandable by the meanest capacity; and I doubt that my familiar style may frequently appear vulgar to more polished eyes and ears than mine. But I take credit for having avoided the use of technical phrases, terms of science and learned dissertation, as well as the crime of over-refinement with which I have rebuked two cotemporaries, whose laughable sublimations are idealized at page 445.

Candour and ability for the task are not always found combined with willingness, even among our best friends, to amend certain slips of the pen, or to curtail such exuberances as the more animated writers are liable to fall into; and I am free to aver, that the friendly assistance I obtained in this respect, did not always second my plain meaning, nor adequately fulfil my wishes, though I am grateful for these and every act of kindness. After all my care, repetitions have crept in, and owing to the length of time occupied in the composition, or rather the manner in which the various particles of information were collected together, and digested into form, great variety of style may be discovered, though unity of purpose, and the desire to in-

(1820.) Since then I observe that some one has intermeddled unworthily with that author, and spoiled his meaning, his arrangement, and his simplicity. The second, third, and fourth editions of that work are the best in all those respects.
STRUCT, pervades every page. The arrangement is at least obvious: the principles being taught in the first book; the details of practice follow in natural order in the second and third books, and seem to arise out of the preceding observations on the animal system of the horse, as regards the origin of constitutional disorders. The references from the latter chapters to the former, operate as exercises with those students who may have neglected to acquire and retain sufficient intimacy with the principles laid down in the pages so referred to.

The diseases of brute animals are few and simple, and easily cured when the symptoms can be distinctly traced up to their causes; for the remedy then consists in little more than putting the animal upon a direct contrary course to that which brought on the disorder (though not too rudely), and health follows. For example, heat, inflammation, fever, is the most general cause of constitutional derangement in the horse: in a state of nature, he seeks out and employs the remedy himself; when domesticated and pampered, or at least denied the use of green food, we judiciously set about reducing the heat by cooling medicines and factitious regimen, and the fever subsides. Again, hard work occasions lameness, rest restores the feet to their wonted state in incipient attacks, topical applications effect the remainder in bad cases.

For the same reasons few medicines are necessary in veterinary practice; but certain modifications of these add to their efficacy in particular
cases; though the school in which I was first initiated, as well as the modern writers, White, and the Lawrences, quite overwhelm their readers with the quantity and apparent contrariety of their prescriptions, which frequently possess no essential variation from others that may be applicable to a whole series of disorders.

Under such circumstances I have been extremely chary of puzzling the reader by merely altering the vehicle when the active material of the prescription had been already compounded for a similar disorder: therefore I have avoided repetition of such (mostly purgatives) by referring the reader to the page where these may be found. Notwithstanding the apparent difficulty of this mode, yet has it certain advantages that outweigh the trouble, and compensate for the moments thus expended. During my noviciate, and long intercourse with persons employed about the horse, in almost every capacity, I noticed that all those who consulted the books respecting any actual disorder, did little more than turn to the prescription which was recommended in their particular case, and it was made up and given to the animal without once more reading over and comparing "the symptoms," and notwithstanding they already had the same medicine upon the shelf. By this blind manner of proceeding, they did but adhere more closely to the old system of their "books of receipts," to the entire neglect of the anomalous symptoms, and risked the mistaking of one disease for another, in many cases. To compel the inquirer
to study his case before he applies the remedy, I at one time thought of adopting the method of La Fosse, and others, who have thrown their prescriptions all together, and referred to each numerically; but, after due consideration, I adopted the middle course, and simply avoided repetition in this respect, as that which best suited with my views of instruction. In some cases, the remedy is mentioned in general terms only; for example, at page 356, I said, "blistering ointment may be applied," &c. The reader will of course, in this and all similar cases, consult the Index; and under "Blistering," he will find himself referred to page 219.

Throughout the volume, though I naturally evaded all controversy, yet in a few instances it seemed necessary to advert to certain existing errors and authorized mistakes; to disabuse the public mind, to negative the mischiefs these were calculated to spread of themselves, and to assure the reader that I was not wholly unmindful of the dissonance of opinion betwixt the authors mentioned and myself.

VETERINARY SURGERY.

BOOK I.

THE ORGANS AND FUNCTIONS OF LIFE DESCRIBED; WHEREIN THE ORIGIN AND SEATS OF VARIOUS DISEASES IN THE HORSE ARE EXPLAINED, WITH A VIEW TO THEIR CURE OR MITIGATION.

INTRODUCTION.—Teachers of the art—Duty of dissecting; its uses and advantages—Method of study—Register of post-mortem examinations;—Application hereof to medical practice.

Of the several modes of teaching the Art of Farriery, the present popular style and manner stands in need of the least preamble or apology, perhaps, for introducing it to public notice, and asking for it the public approbation in its present improved form. The earliest consisted in certain dissections of the Horse by human doctors, which they left the generality of practitioners to study as best they could, with very little aid in discriminating one disease from another, which accounts for the uncertainty of their best medicines doing good. Secondly,
INTRODUCTION: TEACHERS OF THE ART. [BOOK I.
came several treatises on horse-medicine, as Gibson, Bracken, Osmer, Bartlet, James Clark, all well written, according to the knowledge of the times in which they lived, besides many more that deserve notice only to be execrated*. Thirdly, we had the annual Lecture-reading and Experiments of the Professors at Pancras, long time much decried, now discontinued, and never brought within general comprehension, though the pupils from that seminary have published a cloud of Essays, to prove their classical learning. Fourthly, came the popular

* Nor will we contribute our help towards giving them a long lived infamy, further than to quote the opinions of others respecting two of the most noted, viz. Taplin, (a human-body surgeon, as we heard) and Clater, a most ignorant druggist in a borough-town of Nottinghamshire. Of the first mentioned, Richard Lawrence says, in his quarto work of 1812, page 195. "Some medicines that are contained in Taplin's Treatise, are prescribed with so little judgment, that it is an even chance every horse that is compelled to take them dies under the operation." Of the other, we read in Jon Bee's Dictionary, 1824, under the word "Farrier," (page 75.) "The worst-written treatise on this subject now extant is that by one Clater; which for excessive ignorance of diseases, and utter stultification as to mixing of medicines, never was surpassed: let it be burnt by Jack Ketch." A severe sentence, truly, but scarcely retributive enough for the ends of even-handed justice. John Lawrence might have made up a trio, if he really had attempted to be useful in his publications; but John chooses to write "philosophical treatises on horses," which puzzle the very few readers he may induce to purchase, and bewilders himself. White, in his article on "Physic" (Compendium, p. 370.) has proved that John Lawrence knows nought practically on this topic; his prescription of 12 to 14 drachms of Aloes for a race-horse being absolutely a murderous dose; and his camphor with gin and the balsams, to stop the excessive purgation that ensues, confirms our opinion of his incompetency.
method of teaching the Art Veterinary, which all persons might understand who read with care; this was the style adopted by White and Hinds in its fullest extent, and partially by one or two more. Of the last-named, and the volume promulged by him, we come now to speak.

For the reasons assigned in the Preface, in the year 1822, and afterwards, we were engaged by certain booksellers, in publishing periodically an extended treatise on the formation, structure and economy of the horse, as regards his make, shape or built; and to deduce from thence any rational conclusions we might come to, regarding the horse's powers and performances, when those proportions were perfect or agreeing, as well as to shew what were the evils arising from defective conformation. In the course of those investigations, we found that this malconformation, or bad built, as it was termed after the French Veterinarians, was productive of disease of one kind or other, each agreeing with its corresponding evil form with remarkable trueness; whereof the greater number were incurable, whilst some might admit of alleviation, of easement, or temporary remedy. Those diseases of the limbs, by continuance, we also found mainly contributed to keep up the irritation of constitutional diseases that are occasioned by heat, fever, inflammation; whilst the whole series are calculated to originate many others, by the re-action of pain, and difficulty of going, incident to awkward built; in fine, all those which depend on pace, lengths, and the consequent
exhaustion of animal strength, we consider a failure of stamina.

2. The utility of such a study would seem at a casual glance, to end at the beginning, by teaching the reader that he ought to reject altogether such ill-formed horses as might be deemed incurable; but it is nevertheless equally true, that some of those disorders lie concealed from our view at the time of purchase, at least, so that the most wary among us are liable to be imposed upon by art or our own inadvertence; whilst those who study the subject as matter of business will oftener be required to exercise their skill and judgment on diseases that depend on malconformation, than on those which are brought on simply by abuse of the animal powers, by accident, by physicing, cordialing, misusage, or by premature old age; because these are acquired disorders, or inflicted ones; some of which reproduce each other, and after awhile, being further irritated by bad built, they mix together and receive the uninstructive epithet of "a complication of disorders."

Those disorders of birth we allude to, as having such unhappy effects on the acquired disorders, are those of the frame, otherwise termed its conformation. But there are others of the whole constitution, or which become constitutional in early life, that must not be lost sight of; the which, when exercising their malign influence along with any or either of the former, become indeed a real complication, and then only. For the same dissonance of
the external parts of the animal, which we shortly proceed to expound, is recently ascertained to extend to the internal organs also; that is to say, the powers, the size, the capacity of one set, so far outstrip those of another, as to occasion that sort of derangement in the functions of animal life, which we denominate *constitutional disorders*. True, these may be _acquired_ also; but we are now considering original defects, those of _birth_; though some may be undeckly the one or the other, or attributable to both, as we shall see presently.

3. Among these latter, we know the _adhesion of one internal part to another_, as of the lungs to the ribs, is the cause of death to many a fine foal, and young horses in training; we know, likewise, that this is the unaccountable disorder of full grown horses which those persons term _debility_, who are at a loss for a more specific name; whilst others cry out "_worms!_" by reason of the staring coat, and loss of appetite, which are the corresponding symptoms of this cruel and inscrutable disorder. We do not mean to assert, for one moment, that this is a disorder of ill-formed animals only; it is found, after death, to have destroyed the finest and best built horses, on _the turf_, principally, by reason of the very strong work these are put to, accompanied by high-feeding, strong physic, and denial of water.

Thus, it will be seen, that an inquiry concerning _malconformation_, involves the diseases attendant thereon; that the internal structure is liable to the same kind of misfortune; and, although we are not...
prepared to insist too strongly on what we only believe to be the fact, yet are there many internal disorders influenced greatly by external form; whilst others faithfully attend their appropriate co-disorder—as bad lungs on founder, and other diseases of the fore feet. All these, doubtless, it would be a very desirable task to develope, and to accompany each by its distinguishing symptoms, whilst submitting to the reader's notice also the principles upon which the cure should be undertaken. With this impression, we did proceed, at the date before mentioned, with the investigation; afterwards extending it to a Physiological description of the organs of life, their functions in health, and sketching the effects of derangement as we proceeded; still keeping in view the principles of cure, with suggestions as to the proper remedies in most cases,—preserving, however, the details until we should arrive at that part of our labours in which the causes, symptoms, and cure of each separate disorder would occupy undivided attention.

4. Of the proper application of such a study, so began and carried on, to the removal of diseases in the horse, that are thus evidently superinduced, continued, or exacerbated, no one of any consideration will venture to express a doubt, we should think, at this time of day. For example, how the doctrine of adhesion—of the extensive existence whereof there now remains no question—was first broached, or by whom promulgated, we profess not to know for a certainty; having all through life, at
least since a line first fell from this pen in 1801, freely communicated to others our observations and remarks on every topic connected with the Art of Farriery, without reserve. We only recollect an early aversion to horses which stood with the legs much under the carcase, (one of the symptoms of *adhesion,* ) and imagine this to have arisen from a parental admonition, not to purchase horses of such and such a built, (as we come to explain presently) nor to rely upon their going *safe,* much less *in form,* nor upon their lasting at *strong work,* of whatever nature that might be. And this, with close observation on the fact, that some given disorder prevailed most with horses of a corresponding make or built, brought us to the conclusion, that this extended to all other instances of cross-built, hollow back, long body, narrow chest, limbs ill-attached to the body, crooked or disagreeing in length, and numberless other defects. These latter, we found, originated many disorders of the feet before and the legs behind, and always affected the *tread* of either pair—to say nothing about the *form* of going, on which depend pace and speed, and the lasting qualities. We ascertained, in like manner, that the prevalent constitutional disorder of the horse—*inflammation,* was frequently engendered, and always rendered more virulent, by the pain, the labour, and cruel suffering of such an animal, when pushed in his work to the extremity of his powers. To say that those propositions are self-evident, would argue presumption of a too easy
belief in the student of these pages, and supersede the propriety of any further explanation; but that they are demonstrable is not too much to say, seeing the reception our former investigations and enquiries on this head have experienced; though we still hesitate on arrogantly insisting hereon to its fullest extent—as it is apprehended must take place at no distant period—until more mature reflection, and some further experiments, have confirmed the opinions thrown out in the former edition and here farther illustrated. Mean time, the verbal warm approval of many distinguished judges of horses, and the written testimony of others, to be noticed as we proceed, as they confirm our first immature views of the subject, determine the mode of treating it which we shall now pursue.

5. Discussions of this nature, however, that appear first in a periodical miscellany, are necessarily too argumentative, and presuppose too many obstacles that require previous solving, to be particularly useful to the junior student, or the wholly uninitiated; whilst, from adopting a very popular and diffuse manner of treating the subject, we were constrained to turn away altogether from the use of scientific terms which those persons are taught to venerate; and we were further induced to decry those terms as burthensome to the sense, as indeed they are to the common sense reader. In this state those papers went to press, under the title of "The Veterinary Surgeon." We do not say they went hastily, nor that they were at any time crude or ill-digested; on
the contrary, we recollect, with painful pleasure, that those papers contained the result of many years' laboured research; years of long, and dili-
gent, and patient investigation, indeed, that have been succeeded by one of rich communication from others, and with much successful revision on our own parts*. These together, have greatly encreased the former stock of information on all topics connected with our main subject, and induced us to concede somewhat to friendly advice regarding the style of teaching the Art of Farriery to the unin-
structed, or, what is still more difficult, to the half-
taught. Conformably to this resolution, our plan in the present new and improved edition, is marked out, to steer between the two extremes, still re-
taining the familiar illustration and apposite re-
mark, which renders the most difficult arts familiar to the generality of mankind—whilst duly re-
specting the requirements of scientific persons, as to the terms of art and particular modes of ex-
position with which alone they are familiar†.

* We are not ashamed, nor afraid, to confess, that the new doctrines on various topics advanced by us in our former edition were not so adventured without great diffidence; notwithstanding the many experiments, much close observation, and the evidence of our senses, which aided our conclusions. And among these, what regarded, "awkward tread," was already undergoing severe re-
vision, when our attention was called to the coincidence of our opinions thereon, with those of the celebrated Nimrod, in the Sport-
ing Magazine for August, 1828, in which he confirms mainly, and quotes largely, the very points upon which we had thus begun to cogitate. Those quoted passages occur below, at pages 36. 46. 48. 51.

† A "Lecturer on Anatomy and Surgery," writes thus freely,
6. To effect those objects in the plainest possible manner, and to teach without circumlocution the willing pupil, we do not think it necessary, as on the former occasion, to exhort him repeatedly to pay attention to our inculcations; neither to reprove harshly those who undertake to prescribe without taking a view of the beautiful structure upon which their ever-burning, drastic medicines, are destined to act—because we are now convinced that scarcely any owner of a decent horse would call in such a pseudo doctor at the present day. For, since the year we began to write and to examine into the premises, we observed them fast falling into grave decay, or they have come over to the adoption of a more rational practice. Even the grooms, whom James White thought proper to decry on twenty occasions, in his Compendium, have shewn a general disposition to study the sub-

"John Hinds's book, if re-written, might be rendered useful to scientific persons, if it embraced all that is known on the subject; and so impressed am I with its necessity, that I will offer my services in correcting and completing a scientific edition, gratis." Herein, by the way, the gentleman blunders egregiously: if our intention had been to send forth a mere scientific work, we should not have termed our treatise, "a familiar" one; nor have called it "popular," neither have thought it "an easy plan" as well as new, nor addressed it to the "shoeing-smith, farrier, and groom."

Again, he says, "although the book contains some useful information, yet it abounds with vulgar phrases, and unscientific, unprofessional, and bad language." We knew this beforehand; how else could we make ourselves understood by the generality of those unscientific, unprofessional persons, for whom alone we wrote, and whom alone we delighted to enlighten?
jects that pertain to the well-being of the valuable animals committed to their charge *

7. The manner of studying the diseases of horses with the fairest prospect of attaining a commensurate degree of proficiency to effect their cure, we insist is the dissection of healthy subjects, at first. For hereby the student is enabled to ascertain and store up in his memory, accurate notions of the internal formation and functions of the animal system, as they ought to be performed, so as to constitute health. Whilst the post mortem examination of animals that die of diseases, would at all times show the altered state of the viscus, (or part) most affected by the disorder; as also, how this may have influenced any other part, through contiguity, companionship of feeling, or sympathy,—as the inflamed lungs on the sternum (or breast bone) the stomach and kidneys, &c. In this manner only can we put the student in horse medicine on the proper course to be pursued for the detection of anomalies in the symptoms, or teach him how to adapt his remedies to the ever-changing nature of many diseases, and of visceral inflammation as much as any other;—that greatest of all plagues that attends horse-keeping, by its latent effects in reproducing other disorders, as much, or more, than its immediate ravages upon the constitution †.

* We took occasion to advert to this pleasing fact, in the Grooms' Oracle, page vii. of the Preface.
† At the Veterinary Colleges in France, the pupils study in scarcely any other manner than by dissection. Very little pharmacy,
8. Let us, then, once for all, exhort every person whom horse knowledge may concern, to examine the internal state of all the dead horses to which he can obtain access. In or near London no difficulty lies in the way of a full compliance with this recommendation, whilst the neighbourhoods of provincial towns and hunting establishments, afford a sufficient number of subjects for dissection for all purposes. Whatever dislike, or even disgust he may feel at his first entrance upon these examinations of dead bodies, our student may rest assured that this will soon wear off: anatomy becomes the most fascinating study we know of, when the inquirer begins to discover the hidden secrets of nature. Nor is the pursuit at all unhealthy, so far as our own experience goes, as we recollect only one case in thirty years that was offensively otherwise—and this one of putrid fever, in the year 1824, mentioned farther on. [See Index, Fever, Putrid.] Moreover, we recently find, that a commission, ap-

some reading, frequent lecturing, but scarcely any practice of medicine, to which alone, a three years' probation ought to tend, constitutes the whole of the education of army Veterinary Surgeons in the neighbour kingdom. At least, this is precisely the case at the School of Alfort, as they modestly call their establishments. At Toulouse and Lyons, in the southern parts, are similar schools; which we in England more magnificently call colleges. They deem anatomy and physiology all-sufficient. We (in England) neglected it as a popular study, until the last few years; our whole reliance being on physic—physic, right or wrong: the wisest course, as in all similar cases, lies in the medium. The French farriers are, indeed, most inveterate anatomists; a fact that marks the taste for curious minute investigations, to which the character of the nation seems prone.
pointed by the government to make enquiries hereon, at Montfaucon, the great knacker-yard of France, reports that the trade of horse slaughtering is not only innoxious but sanitary.

9. To render his labours efficient to after purposes, our student should keep a paper book or register, ruled up and down, stating in sundry columns the appearance of each subject, so far as regards the vital organs at least, after this fashion.

We will shew presently what kind of entry is proper to be made under each head of information, by way of making a beginning; but he will not be left to grope his way in the dark, if he will study with proper industry the further details to be found in the second chapter of this book. For this purpose, the dead animal being down on its back, two legs on the same side are to be made fast by cords round the fetlocks, to a beam or nail of the shed. Then, with a good tempered knife, let him enter the skin at the sheath, and continue the mark straight up to the breast bone; hereupon it will recede, leaving the membrane of a bluish cast, if healthy, appearing through the fissure. The young operator will be careful not to cut the skin in flaying, for a fine is imposed for every such clumsiness, by act of Par-
liament, Anno 1800, which caught ourselves in its trammels at our very earliest essay. The next cut in the same line permits the gut to protrude, wrapped in its peritoneum, which membranous film soon bursts, and the caecum and colon press upon our notice. Ascertain the contents of the former, which is as large as the stomach, and lies rather to the left side, and observe the passages into and out of this repository of water, &c. Look to the latter, and by its colour judge if the horse has been carried off by inflammation of that part, by jaundice or otherwise. This conceals all the other intestines, (except the straight gut) by a convolution, in this wise:

Upon removing those large guts, let him examine with minuteness the junction of these with one another, which act as so many constrictions, to prevent the too ready escape of their contents. In the case of suspected inflammation, the conjunction of the large gut with the straight gut, or rectum, should attract his notice; as should that of the smallest gut, or duodenum, with the stomach, in every case, and the entry into it of the gall duct, from the liver, which conveys the bile into the intestines. In all cases of death through protracted illness, all of fever, however rapid, all of acute inflammation, he will discern the effects these have had upon this secretion of bile by the liver; whether too much or too little, whether thickened and obstructed, or not produced at all, as in “the
yellows,” or, in what we will denominate “inflammation of the liver.” For, notwithstanding less of heat supervenes than enlargement, yet as nought but undue heat, of stable, of weather, or of constitution, can effect the swelling of the liver, we feel justified in considering this appearance no other than genuine inflammation of this delicate organ, though of the low or squalid kind. See Index for “Fever, low,” where this doctrine is further advocated.

10. In like manner, our student in Anatomy should proceed with every other part which goes to prove the particular disease the animal died of; where his examination must enter into every minute particular. Let the inquiring reader here contemplate the scene that lies before him! An immense animal, admired throughout the whole world for his grace, deportment, and services; nay, loved as a co-being in some parts, though abused and made the topic of humanity-mongers in other countries—exposes to the view of the anxious inquirer, the means with which it has been furnished for prolonging life, for “living in the race,” for adding to its capacity of propulsion, now deprived of motion, and offering the last boon to the man who would ascertain why all those important functions have ceased so soon. He is now examining the immediate cause of death, that he may know how to ascertain its existence in future living cases, that he may apply the proper remedies; or he ascertains the “complication” which commenced its ravages at a remote period, and ought to have been prevented in
time. He will soon perceive that, without this preliminary horse-knowledge, he can never hope to undertake the alleviation of any internal disorder, much less to effectuate the cure of horses with the common chances of success! For we must here observe, that the practice of physic, in any of its departments, is but an uncertain art at best; and that mistakes occur, even in the human practice, much oftener than we think proper to declare in this place.

11. Than this species of examination, we know of nought that can prove so instructive to the rising genius for anatomical research; nor, certainly, any thing that so fully contributes to pathological acquisition, as the after-death examination of a horse the student himself may have attended during life—in its last illness, and final catastrophe. Of course, we presume he has taken care to keep an account of the symptoms, and their changes from time to time, as well as the treatment he may have thought proper to adopt. If he has further noticed the deceased's peculiarities, the conformation of his bones, their coverings and consequent manner of going—the disease to which his constitution was, more than any other, prone—his manner of feeding—his craving for water—and the particular kind of misusage (as to physic, work, food,) to which the deceased had been subjected; and then compare these with the appearance of the organs of life—and, we insist, our student will acquire more valuable information over one such subject, than from opening half a dozen strangers' horses.
12. He will have his ruled register, before recommended, ready at hand, or will take rough notes on the spot, in order to enter them fairly at a subsequent hour; and we will now proceed to instruct him how to fill up the blank columns of his book, profitably and fit for reference at a future day,—when it may be required to be consulted, compared with other cases, and conclusions drawn in some similar disease difficult to comprehend, and rendered dangerous by obstinate continuance. He will know how to appreciate the number of such examinations entered on his register, as so many authorities upon which he may securely rely; though he may not perceive, at first sight, how it must happen that fifty such demonstrations are triple the value of twenty-five, and a hundred worth four or five times fifty—by the confidence numbers inspire, and the adroitness he will have attained in the process when the highest number is entered on his book. Let him keep his accounts how he may, still he must keep accounts of his examinations, if he would make the desired proficiency.

13. A register of the subjects dissected need not contain minute particulars of every-day occurrence, though no important variation should pass unnoticed, especially when this is connected with the loss of life. "Debility," we know, and the often repeated complication, come in for the greatest share; both which mean that the animal has been "done up" by maltreatment, since scarcely one in ten thousand reaches old age. Therefore
must every reported case of debility or complication require the exercise of his honest scrutiny. The adhesion, or growing together of one vital organ to another, is this so-called debility; brought on by the drying up of those aqueous secretions which nature designed for lubricating the parts; all this mischief being the consequence of quick pace, of hot, cold-and-hot stables, and exposure, acting upon the animal's natural heat, having exhausted the moisture, whilst denial of water usually accompanies every other species of mistreatment.

Under "Description of Horse" in the first column of his Register, the young student will, of course, set down whether horse, mare, or gelding; its size, age, and colour. Perhaps state conformation or built of the individual—whether long-bodied, hollow-backed, or roach-backed, thick head, cat-hammed, &c.

2d. "Disease." Add hereto doctor's name and treatment, if known.

4th. Stomach. Open and turn out contents, examine the medicine herein and in the cæcum. Note the gastric juice, the secretion whereof continues long after life is extinct, if the animal has not suffered long illness previous to dissolution; and which, falling upon the lowermost exposed coats of an empty stomach, there corrodes, and occasions an opening, when its contents are found dispersed
among the intestines, which most examiners attribute to poison. Hence the caution that is necessary in pronouncing any body to have been poisoned; for hence have arisen some frightful errors. Compare contents of cæcum and stomach. Note its size, relatively to other organs. See Stomach, in plate of Skeleton, I to L, 26 to 29.

5th. Liver. Its colour, high or low; spots; perfectness at the lower extremities. Whether adhering to diaphragm or to bowels. Gall duct, how attached to small gut: size. See it in the plate, G to M, 23 to 30.

6th. Diaphragm. Mark state of its skirt, if inflamed and enlarged, pressing on the liver; adhesions on the lower side. Prick it, and see to its upper side for the same.

7th. Lungs. Colour—spots. The pleura and mediastinum how attached to the bones: the latter how adhering together. Perfect or not. Pulmonary action; cells destroyed.

8th. Windpipe. Slit up and examine lining, as to broken wind; and note state of epiglottis and bronchiae, concerning which the doctors disagree.

9th. Heart. Open its bag (Pericardium.) Note the quantity of water, or its absence. Trace its vessels to the lungs.

10th. Kidneys. Look for concretions. Examine pelvis of each, and note state of secretory vessels; the ureters and their connection with the bladder.

Much more remains to be done; but we press no more upon his notice at present: the circulation, lactification, digestion, and respiration, which are carried on by the organs of life just enumerated, are traced upward, from effect to cause, in the second chapter. In that chapter he will find ample means for enabling him to make the most profit of the examinations we are now recommending him to pursue. He will there meet with frequent references to the skeleton of a horse which stands at the front of the present volume, and with which print we presume he is already somewhat acquainted; by consulting what is said of it at pages 22, 23, and 24, he will learn more.

14. Although his enquiries should proceed no further than this slight kind of examination comes to, the acquisitions thus made would at all times give the industrious enquirer immense advantages over the practitioner who continues to give his strong and, therefore, destructive medicines without caring to take a glance at the parts on which they are destined to operate. At the very lowest estimate, the student will hereby ascertain what are the appearances of those organs when the functions of life have been duly performed; for it is not too much to suppose, that he will meet with some horses which have died in comparatively good health, through accidents on the road; and compare those with the appearance of others which have died after protracted illness, through some well-known disorder, or in consequence of improper
medical treatment—both being equally destructive. But we shall shortly enter into more minute details—not indeed so minute and particular as the subject is capable of, but quite sufficient to enable the student to commence these examinations with pleasure, so that he may derive as much profit from this labour as will fully serve his purpose herein. He will hence learn how to appreciate the value of the remedies we come immediately afterwards to propose for the cure of disorders thus accruing; as he will, also, in the course we mean to lead him, see the propriety, the humanity, of timeously preventing many of those disorders from making head, and committing those dreadful ravages which are inflicted upon this valuable animal; or, in other words, are acquired unfairly, through mistreatment or abuse of his powers.

15. In this latter respect, what mistakes occur, what mischiefs are perpetrated! Whereas, much loss would be prevented and some just reproaches avoided, by putting horses to that labour only for which, by the nature of their breed, they are best adapted; neither to expect fleetness or strength beyond a certain extent, where the gift of fleetness, or surpassing strength, is denied to the individuals under consideration. For example, we do not run a horse that is lame!—then why work him until he falls lame? We do not expect a tender horse to stand exposed at the covert side with impunity;—then why take him thither at all? Or, if he be ill-formed, we cannot reasonably expect him to go
well over ploughed land, and "live to the end of the chase." Better reject such entirely—at least for those purposes. Then again, horses of a certain conformation of the bones, which we call shape or built, never can perform any service properly, some not tolerably: but we may study such an evil form rather as a stumbling-block to be avoided, as also every approach to such a form, lest we get disappointed in our hopes; and our present investigations tend to ascertain, as near as may be, the simply objectionable shape as well as that which is intolerable.

Explanation and practical use of the Skeleton, (or Plate 1) annexed as a "Frontispiece" to the volume.

The references that are made to the annexed plate, and which will necessarily be found rather numerous in the chapter on conformation, are so made by means of letters and figures, corresponding with similar letters and figures, upon the plate. The letters direct the reader's eye across the picture, as the figures do from top to bottom: when he is referred both by letter and figure, the place of intersection is the point to which his attention ought to be directed. Thus [F. 36.] which by placing a flat ruler, or a piece of paper, across at " F," and running the finger downwards from the figure " 36," would be found to intersect each other at the insertion or commencement of the
horse’s tail, two tail-bones being concealed in muscle; whilst [Y. 40.] would bring us to the hindmost pastern, as [Y. 14.] does to the foremost pastern. Again, [K. L. M. N. 14, 15, 16.] or [K—N. 14—16.] directs the reader’s attention to the shoulder-bone; at [M. 20.] is his heart, and at [H. 29.] his kidneys are placed.

The reader will please to observe, that the Frontispiece is meant to be, less what is termed “a pretty picture” than a practically useful one, well calculated to facilitate his comprehension of what is said in this treatise about the living horse, his structure, and internal formation; of his capabilities and all of the diseases arising from their misapplication. To this end, a mere elevation of the skeleton was requisite; and, that this should be rendered practically useful, it is placed within parallel square lines, for more ready reference. The figure itself, is that of a rather long-bodied hunter; the blade-bone having been depressed to show the continuity of the vertebrae, or backbone, between the shoulders, and the elbow is bent forward for that purpose, so that the shoulder-bone (or humerus) is brought to form its sharpest angle; whilst the same pressure occasions the first six vertebrae, [at E. F. 15—19.] to lean backward inordinately, the fourth, fifth, and sixth, being also a little higher than common. This position of the limb, of course, rendered the subject of the plate lower before than he would be were those bones left more straight up and down than they are here represented. - See Section viii. Chap. I.

The reader will observe that the ribs, eighteen in number, are connected with the first eighteen vertebrae of the back-bone, i. e. from the first at F. 15. to the last of these at F. 27: behind this are the six vertebrae of the loins; next the hip-bone, or pelvis, formed internally basin-fashioned. In fact, this bone in very early life, is composed of several bones, which afterwards knit together; as do the five vertebrae next behind the pelvis (in the parallel 32 to 35,) form but one bone, though here shewn distinct like a colt’s. In like manner is the bone of the face divisible in early life, at the cracks, or sutures, underneath the eye. The bones that together form the back, have each a sinuous process, that varies greatly in quantity at the withers; and this is further affected by the shape of the whole back, spoken of in the 12th Section, page 56. All those bones of the back, and neck are so connected as to form a secure canal for the spinal marrow to pass through its whole extent, from the head to the tail; in its course sending out the nerves to every part of the body. Hence the reader will see the
vast importance of a just shape to the due performance of this function, so essential to the animal’s lasting qualities.

He will observe, too, that the situation only of some internal parts was required for the purpose of elucidation; thus, the heart seems unsuspended by its vessels, as its pericardium and part of the lungs are removed; and it follows, that whoever expected to find a delineation of every viscus, perfect, has deceived himself,—if any such there be.

The Lungs are here represented about half inflated [I—N. 15—23.] and would fill the whole space above, to where the diaphragm, or midrift, is stretched across from the back bone [at G. 27.] to the first true rib [at N. 22.] But here the acute observer will remark, that the lower end of the lungs obtrude beyond their natural healthy position. Disease has, in this supposed case, made considerable ravages; adhesion of the lungs to the muscular border of the midrift, (vulgo skirt) having caused this latter to enlarge on its lower side towards the abdomen.

Further, the references our readers will meet with in the midst of the text are necessarily as brief as they are useful, and are made to the sections, or parts, into which the first two chapters are divided, after the manner of verses.

This mode of reference will be found highly serviceable to his investigation by the attentive reader, who is unused to study things of this nature, but who must soon perceive the great practical advantages to be derived from so intimate an acquaintance with the subject as this method of learning it will furnish him the means of acquiring. If, in the prosecution of his studies, he happen to forget what has been before said, tending to the same point of information, or he be at a loss whereabout he should look to refresh his memory, these references supply him with the ready means of overcoming the difficulty: in all other cases he must consult the Index. By adopting this method, we have likewise avoided the repetitions inseparable from a work of this nature, and have thus saved room, and the reader’s time, though not our own labour.

* * Terms of art left unexplained in the text, and other hard words, will be found with their meaning explained in the Index. As to the anterior and posterior of the horse, we have adopted the upper and the lower, as being more generally understood. See page 86.
CHAPTER I.

External formation or structure of the Horse, and the disorders originating therein.

Section 1.—Scarcely any man who is in the habit of seeing many horses perform their labour, and of observing their capabilities of several kinds, but acquires, thereby, some insight of the properties conferred on the animal by such or such points of conformation. He can tell, at first sight, nearly from this habitude, "what a horse can do;" but few men reduce their observations to writing, least of all to principles, upon which we may afterwards reason, or draw conclusions with any degree of certainty, as to what duties a horse cannot perform properly, when wanting those points of excellence, and which duties ought, therefore, never to be required of him; or, being so imposed upon him improperly, are productive of certain disorders that invariably attend such misapplication of his powers. No doubt it has happened, that a speedy horse with a radical defect,—in the shape of his hind quarters, for example,—yet having a corresponding defect before, the one makes up for the other, and such horses may occasionally perform well for a short time, but then they are no lasters: all the while they may thus be at the
full stretch of their physical powers, straining to the utmost the immediate coverings of the bones, something or other is going to wreck—of muscle or tendon, of ligament or sinew. Sooner or later, the effect of so much excessive fatigue of the deformity runs along the solids, and reaching the vitals occasions constitutional disease, or leaves behind it an incurable malady, mostly descending to the feet, and to the fore ones in particular. Equally true is it, that we frequently find out new properties, or hidden powers in a horse, which had never hitherto been known to his owners; but, then, as I shall particularise by and by, no such latent powers were ever discovered in any horse, without his possessing certain just proportions of the bones taken altogether*. What these proportions are, as well as what they are not, I come presently to lay down; the integuments (or coverings) ever adapting themselves thereto, in one case produce what is called symmetry; but, if the limb be disproportioned, the coverings adapt themselves to that particular defect, and enlarged muscle at these particular places becomes visible to the commonest observer.

The acquiring a ready mode of discovering when a horse of the one or the other formation is pre-

* Eclipse, a horse whose very name is synonymous for speed, had none of the proportions generally deemed indispensabile to great speed; and he was cast, by the Duke of Cumberland, for his apparent deformities, when a colt; but his defects in one particular were amply supplied by excesses in another, and, taken altogether, composed the very best bit of bone, blood, and muscle ever produced.
sent to our notice, forms the perfection of art in passing judgment on a horse.

2. But the horse's achievements, or "what he can do" under certain circumstances of shape and make, would ill employ our pen at the present moment—valuable as the investigation must always be in itself—were it not for the practical application we mean to make of it shortly, by way of illustrating the direct contrary, or defective shape and make, as being the harbinger of several radical disorders of his frame. Nor is this all: some are so evidently ill-formed in the chest and carcase, from the moment they are foaled, that no art of ours is equal to prevent the return of certain disorders which are sure to attend a horse of that particular formation all his life-time. As the one is known and inevitable, so the effects of the other may be foreseen, and, in some degree alleviated, if so much trouble and expense be not greater than the value of the horse. This is all that can be done for such an animal: and since the resources of art are not equal to the obstacles of animated nature, so no man ought unreasonably to expect, least of all, to force his beast, to perform any species of labour or exercise, for which nature or the accident of birth hath rendered him any wise unfit; although it must be allowed, as a general axiom, that it is only by pushing the animal to the extent of his powers, that we can find out the most he is capable of performing at any given work. In this way it was the fast-trotting powers of the Phæomena mare (which was before
then a butcher's hack) were discovered; for people of this trade generally try the utmost their nags can perform in the trot.

To be able to judge of a horse's defects as to what he cannot do, undoubtedly it seems necessary to ascertain what constitutes a fine figure, or a perfect one, that can do every thing; but, when it is considered that the exposure of those defects is intended to apply wholly to the origin of disorders for which he will require medical treatment, if he does not deserve rejection in toto, we shall find less occasion for adverting to any known horse, entirely without error in his form or built. In most cases, however, good symmetry being accompanied not only by the power of achieving great feats, but a good portion of health also, or at any rate, the absence of the diseases incident to a bad form, we may be allowed, while exposing his faults, to deviate a little, and to contemplate some few of his perfections also.

3. The most obvious physical truths are those which can be explained upon the principles of mechanics*; upon such a basis, even the more

* Sir Charles Scarborough, it seems, was the first doctor of medicine who introduced mechanical and geometrical reasoning on muscular action; but we had never heard of him, or any person employing this means of elucidation, until several years after the passage in the text was printed. Sir C. S. delivered lectures for seventeen years, at Surgeons' hall, from 1658. After much enquiry, we are led to believe that no one followed Dr. Scarborough until we of these times. Since our first Edition, however, that highly gifted body, "the Society for Promoting Useful Knowledge," have followed the same mode of instruction, in the 9th No. of their Tracts, entitling it, "Animal Me-
abstract can be securely grafted; that intelligence which is derived from experience, from observation, experiment, and acute reasoning, being rendered more understandable when conveyed with mechanical precision; and, however strange it may appear to some, the gift of speed, if not of all *progression*, depends more upon mechanical principles than is commonly understood to be the case. See farther onward, at *Section 9*, where further details are given. In all compound bodies, whether animate or inanimate, intended for our active use, it is above all other things requisite that they should stand well upon their bases or legs. A horse, or a joint stool, evidently defective in this particular quality, would be shunned as insecure, and the one is sometimes endued with *movements* as little suited to one's ideas of getting on safely as the other; both being indebted to its original bad *built* (or *charpente*, as *Lafosse* calls it) for the defect. Cover them both, the one with *muscle* and *skin*, the other with *morocco* and *drapery*, how you will, the faulty legs are faulty still. As to this point a good stable *aphorism* has it thus—"a horse that does not stand well can do nothing well;" and, by a very natural inference, "the horse that walks well can perform all other paces well."

A much better example, however, may be found in a *four-legged* table, of which every horseman knows there are many of different sizes and of

"If we required justification for the views we then took, we should turn for it to the first three columns of that tract."
various workmanship, some for heavy work, or rough usage, others more for show, and to sustain light weights. But, if the fore and hind legs bend towards each other upon the ground, (like cut 1.) any carpenter may see that this first element of visible ill-formation must sooner or later produce a fall; he will know, that more strength for supporting great weights would be produced by making all four legs perpendicular. But a horse, not being like a table, immoveably fixed upon its legs, and being required not only to bear up but to proceed with his load,—which is sometimes effected with difficulty on account of its weight, then must his powers of pressing onwards be estimated by the positions in which he can place the bones of his hinder part, the legs particularly, since it is to these the propulsion of his body forward is chiefly indebted. In his efforts to accomplish this duty, the position of his hind legs will resemble those of the second cut in the margin, stretched out constantly as much as these are, and each leg alternately twice as much beyond his body; while his fore legs will bend under him alternately also, like those in the first table. In both movements his legs are stretched to their utmost when the heavy drag is up hill;
because the resistance to be overcome is then greatest, and we can thus form an opinion how much "he has the free use of his legs." When this is the case, all horses step short; but, upon even ground, the hind leg, to be perfect, should come firmly forward in the walk, and occupy the identical spot which the fore leg had just quitted. See further at Section 8. As the horse gets old, is tired, disordered, or over-much laden, he ceases to do this as usual, in the exact ratio that he is affected the one way or the other.

When age overtakes an animal, we may rest assured some of the evils of a too long life attend it. The heavy work which the horses we have now chiefly in view, are put to, strains every joint, of the hind legs principally; as high as the setting on of the leg to the pelvis, [I. 35.] or the juncture of this bone with the last vertebra of the back, [E. 31.] and even the back bone itself, this species of ruin works its way with years, upon fine, strong and robust horses, as much or more than any other. Then it is the hind leg comes forward much farther in the walk than in early life, and it acquires a twist or screw, which is denoted by a screwing, markedly, upon the ground, and visible all the way up in bad cases. Speedy horses have the same screw in going, though not so apparent, when the limb is similarly strained; but in some cases great aridity of muscle, the effect of hard work and want of care, amends trivial strains, whilst the tread also becomes shorter.
4. Mares, occasionally, and skittish horses, frequently bring their legs together, much resembling the first figure, and are insecure roadsters as well as poor draught horses. When it comes on the horse of hitherto even tread, without other accountable cause, we may rest assured, that it lies internally, and is owing to the adhesion of the parts, as spoken of elsewhere. See Index. The second sketch is the walking motion of an unladen cart-horse, or a coach-horse standing still; these, as well as hunters, take the same position, at rest, which indicates that they have the free use of their limbs.

In the drag, the former bring their fore legs under their bodies, the principle being applicable to any quadruped performing the like task; and such a horse would consequently fall down forward but for the resistance of the load he draws. But this accident seems provided for, by the power the horse has of contracting the muscles (see Section 10), and drawing up quickly the lower part of his limb, in time to get it out of the way of his hind leg, both motions forming each a separate effort toward progression. I still have in view a walking pace, all other paces being no other than modifications of the walk; and, in fact, "a horse that walks well can do any thing else well," an aphorism that is a-twin with one equally well founded in the preceding Section.

With some horses, the hind foot, instead of coming forward, as described at the bottom of the last Section, upon the spot of ground marked
by the fore one, falls short of the mark.—These never turn out fast ones, although their fault does not always consist in the shape or disproportion of the bones, but in the contraction of muscle or of the tendon (see this tendon described under the head of "Foot"); at times it is owing to the relaxation of the immediate coverings of the bones, described at Section 16. Such horses may be well enough to look at, but cannot perform properly. The extreme of this misfortune is termed stringhalt; but every approach towards it, however trivial, is good cause for rejecting the animal. In case of the hind foot coming too far forward (in the walk still) and striking the fore one, the fault lies in want of sufficient strength (or quickness) in the fore leg. If the hind foot comes down sometimes inside at others outside the just-quitted situation of the fore foot, the animal has a disagreeable rolling in his gait from side to side, the fault being as often in the fore leg as the hinder one, sometimes in both. Such horses commence a journey with much apparent confidence, but tiring soon, they fall into their old error, and the security they have inspired is found to be deceptious:—many accidents are the consequence. This fault I hesitate whether to ascribe to the fore leg or the hind one, but it certainly originates in a disagreement between the fixing of the two upon the body, either as to the situation, or want of muscular strength at the place of joining. Such a horse is a stumbler, and when he trots away from us, we can see nearly as much

CHAP. I.] IN THE WALK, TROTting, RACING. 33

c 5
of his fore legs as of his hind ones; in the straight-built, well-set limbed horse, the fore legs are then concealed from our sight by the hind ones. I own this is with me a grand criterion for judging as to a horse's capability of going over the ground. In racing, or indeed any running, the fore legs are then brought closer together, the hind legs rather wider (so in leaping), as we see in grey-hounds, hares, deer, and all other fleet creatures.

Such as I have described is the act of progression with all horses, but in various degrees, according to their sizes (as with the coach-horse, saddle-horse, poney); four such efforts having called into action all the bones of the body, including more or less that of the head, tail, and neck, according to the pace, or other circumstances.—See Section 11. Hence it must be clear, that to perform this duty of progression, or getting forward, properly, as regards either the length of time he sustains it, or the quickness of performance, weight, and velocity, the limbs must be adapted to the kind of work the horse has to perform, and to each other, whether that be in harness, on the turf, the chase, or the road. It follows, naturally, that if we bear-up a horse's head, or cut off his tail, some part of this exertion must be thereby abridged.

5. We do not find this adaptation of the limbs so much in the amount of covering the bones may have on them, as in the size and proportionable-ness of these, and the suitable manner in which they are fastened together; as may be seen in
those horses (blood) where tendon supplies the place of muscle, and most strength resides in the smallest compass; and, as may be proved by the obstruction to his paces, which is always observable in the horse burthened with very muscular shoulders. Equally true is it, that, after we have approved of the proportions of a pair of horses in respect to bone and built, certain powers of going, or of lastingness, are frequently discovered to be possessed by one so much beyond his match, that we are compelled to admit those powers do reside in something else than in his built. Superior health, sound wind, courage, give this strength, with speed and lastingness: the bones being then well cased together, and strongly supported by their immediate covering, have full and fair play*. But wherever they be fundamentally ill-adapted to each other, in whatever degree this escapes our observation, the muscles and tendinous parts adapt themselves in some measure to that lamentable kind of form, but which no filling up, or after-accommodation of the parts to each other, can completely eradicate, though it may be concealed from our view. The muscle that is so perverted rises up in the middle preternaturally, as if some sprain or other had caused that appearance; the

* Firing is supposed to restore derangement of the integuments, by causing inflammation and contraction thereof upon the bone so as to embrace it more tightly. This is effected by much of the muscle being taken up into the system, or sloughing off in the cure; as well as the contraction of the flexor tendon (back sinew) and its sheath.
contiguous parts, consequently, undergo greater fatigue than, in the event of finer symmetry, would have fallen to their share; and the extraordinary friction or working thereof, occasions, at a day more or less remote, the exhaustion of its moisture (see Section 21) and the lodgement of acrimonious matter in the cellular membrane, which appears in the form of tumour, &c. This protuberant appearance of the muscle is most visible at the stifle [N. 30], and on the shoulder [M. 13] just above the elbow, whilst the horse is going fast.

A more minute inquiry, however, on those points would lead us away—too far from our main purpose, at present; let us, therefore, return to notice, in the first place, the structure of the legs of such horses as, by their untoward position, entail on them the chances of producing some one or other of those evils that are known to afflict certain horses, incurably, to the end of their days. Thus, some are known to tread on the inner quarter of the hoof, others on the outside, without the real cause being ever ascertained, and remedies are frequently applied that have not the remotest chance of achieving any good, on that very account. Some horses "cut," in consequence of treading on the outer quarter; on the contrary, by punishing the inner quarter in treading, others contract a disposition to "quitter and ringbone;" both instances of mal-formation, or bad built (as we call it), produce splents, diseases of the frog, of the sensible sole, and of the coronet, as the case may be: how it
is, that the various modes of wrong tread are brought on, remains to be examined into hereafter. Meanwhile, it may not be amiss to observe, that the right mode and make may be discovered by noticing the proportions of those horses, that, by the acknowledged just symmetry of their bones, the agreement in size of one limb with another, and the faultless manner in which these are attached to the body, go tolerably free from any such diseases, until old age, accident, or the misapplication of their powers, bring on disease.

6. There are, then, three kinds of mal-formation, or bad shape, attendant on the limbs of horses, which I consider original faults; those others to which they give rise being but secondary ones. 1st. That wherein the leg is ill-formed in itself. 2d. When it is badly joined to the body. 3d. When the fore legs disagree with the hind ones in length or quantity. Each, being attended by its respective defect in going, as to safety, speed, or strength, and liable to incur one or other of the ills enumerated, as appearing on the legs and feet—is worthy of the reader's separate consideration; although it frequently happens, that an individual horse is afflicted with all three faults at the same time, the two first being found together, subsequently producing the other also. But I have generally noticed, that one of those faults sometimes accommodates itself to the other, amending it considerably; as, when a limb that may be too long is set higher up on the body than is esteemed
right construction, in the same manner as a horse lame of a leg may be passed off for sound should the corresponding leg of his body also fall lame. Much the same is it with the third kind of disagreement, in the opinion of many people; because it has existed in some celebrated horses, and they would have us believe that this very disagreement was itself the cause of the celebrity those individuals arrived at. This, however, was not the fact.

7. The Phænomena mare, unquestionably the first trotter of her inches in our days, never did her work in style: nobody could account for her achievements upon the view, and we had always our doubts whether her's was a fair trot, though we won upon her. In the trot she had an unaccountable shuffle. She was low before, but had the gift of taking her fore feet out of the way of the hinder, which fell (in the walk) about half a shoe beyond that of the fore ones, the feet reaching the ground in succession, like drumsticks.

Laertes, a well known grey horse, which was hunted in Leicestershire, 1818, 1819, of no particular powers any where, and confessedly clumsy in the fore hand, without much fire, was yet in the habit of taking the ordinary six feet leaps with ease, and clearing a ditch of twenty-five feet with pleasure, often exceeding those admeasurements by nearly a fourth. Eclipse is known to all of us (as matter of history) for having had a low shoulder, which gave his fore quarters an awkward appear-
ance: but this was compensated for by the fine form of his hind quarter, which, being particularly strong and muscular, threw his body forward at every leap in despite of his low fore quarters,—for running is no other than the leap reiterated. One leading characteristic, however, denoted all three horses to be of the right stamp in the main: they stood even on their leg bones and the soles of their feet; that is to say, straight up and down, nearly, from the elbow [N. 15.] to the ground before, and from the stifle-joint [N. 30, and 34.] to the ground behind, respectively; both those parts, viewed sideways in the plate, being placed nearly horizontal, as regards each other, on the line [N].

But "the shoulder of Eclipse was a low one," say the published accounts of him; yet, as this defect, real or supposed, consisted in the inclination of the humerus, or shoulder-bone [K to N] above the elbow, by reason of the great freedom of the muscles which held it and the scapula, or shoulder-blade in position, he would, when stepping out with the fore leg, rise higher than when he stood still; a particularity that is reversed in horses whose shoulder-blades are set on more nearly upright than those of Eclipse were. This accounts for the vaulting manner he had, as we read in the accounts of his exploits; and his running greyhound fashion, with his chest close to the ground, for he would thereby keep off the ground longer betwixt each leap, until the impetus received from his hind legs was nearer spent than it would have
been but for thus holding up his fore feet. On referring to those parts in the plate of a skeleton they will be found thus drawn.

8. In the next place, Reader! Viewed in front, the fore legs, upon which the safety and ease of the animal's going chiefly depend, should, to be perfect, be widest next the chest; approaching each other gradually, until the eye, having compared that part with the pastern, scarcely perceives the difference. Here, the leg, taken by itself, is smaller, though the interval between the knees and the feet do not differ, on account of the width and flatness which ought to exist in the well-formed knee, yet, taken on the outside, considerably more breadth will be found above than below. Such a knee, when flat and finely marked at the joint, is always strongly covered in a healthy horse, (see Section 15); he then throws it out with great freedom, and takes a firm step fairly on the entire bottom of his hoof; but, should the leg be ever so good an one in itself, yet if placed too high upon the chest, where it is held, not by a socket or insertion of the bone, but by strong elastic muscle only, this throws the feet too near together upon the ground; the horse then treads on the outer quarter of his hoof, and wears away the wall; and, when tired, is most commonly given to cut. Endeavours are used in
shoeing to amend this fault, by paring away the inner crust; but it is one of those defects in *the built* which no art can eradicate completely, and has been termed "pigeon-toed." A *temporary* remedy, however, is found in *shifting the shoes* so worn away, as well as making the shoes thickest on the wearing quarter.

Nor is the matter rendered any better when, by reason of the knees or houghs turning in, the toes turn out, and the horse then treads on the *inner quarter* [see fig. 6.]; and, however those of the one or the other description may have the reputation of great speed, it can be for a short distance only, because the action of such horses must be laboured and imperfect, particularly one of the latter kind of make. He must, consequently, fatigue himself more at every step, and tire sooner than one of the same size, and formed in every other respect similar, but having legs that come nearer in shape to those in the annexed sketch [fig. 3]. That such **knock-knee** form is occasioned by weakness, is evident from the position of the knees, when the animal stands at rest. This he does by supporting himself at times like a dancing-master, with one foot before the other; and, no doubt, the twist with which his pace is always attended when going, occasions certain disorders of the feet, which he seeks to ease by shifting the weight now from the one, now from the other foot. He will, moreover, sooner "knock up," and "get done for" earlier in life, by reason of the origin of this species of mai-
formation being seated high upon the limb, thereby incommodning the action of the shoulder-muscles: the elbow, at N. 15, by being pressed close to the ribs, having thrown in the knees, receives, at every step the leg takes, a kind of double motion, which, of course, doubly affects the action of those parts; and much fatigue, pain, and anguish succeed each other until it communicates to the cavity of the chest. Such animals have frequently the shoulders unusually muscular, hiding, in a good measure, the original defect from the eye and touch of the common observer; but it may, nevertheless, be ascertained to exist, by the symptoms just now mentioned, as well as by the appearance of the protruding muscle before noticed, at page 36. To knocked knees and inside tread, let me add the circumstance, that such horses have a broken pace, kicking loose stones before them, with a certain rolling from side to side, to the great annoyance of the rider. All this arises from awkwardness, by reason of the shoulder's bad position, whereby the leg, being thrown sideways, removes the foot in an increasing ratio from the centre of gravity; and, instead of its being thrown straight forward, describes part of a circle, more or less curved, according to the amount of the original defect. The straight dotted line shows the space a well-formed foot, such as belongs to the leg in our preceding sketch (3), would take, being on paper just

Fig. 4.
one inch; the curved line shows the course, or nearly so, the foot is thrown which belongs to an ill-formed shoulder, that is contracted at the elbow; as this line is an inch and an eighth (or, 1 in. \( \frac{1}{8} \)) in length, the horse so formed does an eighth more work than one with straight legs would do on going over the same ground. See feet of fig. 6. also; cat-hammed, and knocked knees being similar disorders, but never appearing together.

In addition to his other evils, a horse with such a shoulder (being muscular) is most liable to contract "fistula in the withers;" but, if not so muscular, "strain of the shoulder" is likely to attend his twisted manner of treading, when hard worked. With such a built horse, "splents" are usually more tedious than with a straight-limbed one; and strains of the sinews, i. e. of the tendon, as well as those of the coffin-joint and navicula happen oftener, and appear with worse symptoms, in proportion as the limbs are more or less cross-built *.

9. Long and sloping pasterns [Y, 13, 16, and Y, 34, 40] partly denote the Arabian blood, are handsome to view, and make easy goers; but horses of this built soon tire, and, we may say, are generally weak, having the flexor tendon, or back sinew, considerably relaxed, so as to render such a horse "a high goer." The small pastern, or bone inserted

* Respecting "Navicular diseases," and strain of the coffin-joint, here adverted to, in conformity with the prevalent vulgar notion, the reader will turn, profitably, to what is said on this debateable topic, in book iii. chap. 1. as to the section of a Foot, there depicted.
at the hoof, always rises in a direct line from the hoof, both being about 45 degrees for saddle-horses, [see fig. 5.] and the large pastern is then several degrees nearer to upright. These hoofs stand of an oval shape, and have small well-marked frogs. But some, as draught horses, have large frogs, the hoof round, and more upright by nearly ten degrees in early life, as marked in the annexed scale, in which case they are liable, if no change takes place, and they get older and weaker in the joints, to "knuckle over;" but, getting aged, and the supply of nutriment for repairing wear and waste falling short, the heels contract, and the horse becomes pommice footed. The wall or crust is then lower; and, as the bottom of the foot grows convex, causing the animal to slip about, so the front of the hoof becomes concave in time, the toe almost turning upwards, or cracking. Such horses pull no more than their own proper weight, and nothing by their muscular powers, being incapable of making a purchase with their toes.
Horses calculated for heavy draught have short pastern bones, the small one entering the hoof upright at the coronet in early life, but afterwards changing as was said before; and this new inclination, it will be seen, must depress the bone, as the animal acquires the sort of hoof called pompomice-footed, and causes a constant straining upon the coronet; hence ringbone and the crippling, insecure gait, horses of this description acquire, even before they get old; and hence, also, those numerous disorders of the sole, arising from contraction of the heels, that have but this one fault for their common origin.

*Contracted heels* of this or any other species of horse, being thus destructive of its capability of going, should be guarded against as much as any other individual misfortune to which he is liable: even a disposition thereto constitutes sufficient ground for rejection. When this is the case, the interval or *cleft* between the heels, seen in the annexed *scale*, is found to be more or less tender, according to the progress of the disease; the *cleft* will, in health, receive two fingers lain in deeply, the part having in it nothing unusual in the feel. Soon, however, the heat increases, the part hardens, and the *cleft* scarcely admits of a small finger; the horse flinches as if you touched a sore, and nothing but time and treatment can restore him, if any thing can. Most commonly, however, the disease proceeds until the *clefts* of the heels meet and become rotten. *Pressure* upon the frog, with
moisture, is the certain preventive of contraction. See "Foot."

When the pastern-bones (great and small) rise one above the other too uprightly, the small one receives the whole concussion, and communicates the jarr to the very minute construction of the internal foot. See section of Foot, in book iii. chap. 1. The jarring of his pace is then very great, both to the horse and his rider. Such horses are very liable to go lame occasionally, but they recover by rest: the principal damage is to be found in the sensible sole. The ass and wild horse (poney) are thus formed; but being hardy, and having less blood and less weight of body to carry about, suffer less by it than the horse.

The just form or elevation of the hoof in front, upon which mainly depends its form behind, has been discussed by various writers, but remains yet-awhile uncertain and unsettled. Mr. Bracy Clark judged 33 degrees of elevation from the ground to be the best form of the hoof, and Mr. White quotes him with a portion of approbation, but most unaccountably refers to his "plate iv," on which an inscription tells us the fact is not so, but 45 degrees is the best possible elevation of the hoof; whilst those which are higher (lower he writes it, or "33"), "approach too near the perpendicular;" the figure on the plate being wholly different from the diagram on the page (305) of his book, 12th ed.*

* The perpetuating of error, even in figures, the most simple mode
Our ideas, however, on this subject are not so fixed; for we have found the best form of the hoof differ, according to the shape of the two pasterns, as they regard the hoof and each other; deeming that the best, in its particular case, where the small one follows the same declination as the hoof, and the large pastern ascends twenty degrees nearer to the upright, as before stated.

The preceding figure shews the outline of three feet of different degrees of elevation; two of which are dotted in the line of the coronet, or orifice, into which the thickest end of the small pastern-bone sinks, and rests upon the springy substance attached to the inside of the hoof; and which bone, we naturally expect, should ascend out of, and take the same direction as the hoof whence it springs. Any departure from this rule of nature is clearly an approach towards disease. In the paragraph above, we shewed what mischief might be derived from an

of explication we know of, would astonished the more complex reasoners upon abstract questions, if they were not the first persons to over-shoot their own mark in their eager pursuit of nice distinctions and fine drawn arguments. In the face of the foregoing correction of two writers of repute, and with the book and page before him, does the excellent good judge, Nimrod, whilst quoting largely from our labours, commit a similar blunder to that of Messrs. White and Clark. He quotes this opinion of ours as 35 instead of 45, and yet farther onward he quotes from the concluding sentence at page 48, but there preserves the right number of degrees, viz. 45. We do not charge this upon the unknown as an incongruity, but merely adduce it as a tame blunder in copying us without duly weighing the affair,—a mark of deference for our statements we neither expected nor think desirable.
upright small pastern, such as would suit the largest outline (fig. 5); of course, this elevation, or a greater, would be a mis-shapen hoof as well as pastern. In like manner, we know that the low pommice-foot is out of point and diseased, and it follows that the best possible elevation of the hoof must necessarily lie in the medium of those extremes, which we know to be diseases in themselves: this it is to determine a contest mechanically, without once adverting to the well-known circumstance of the health and free use of its heels, which attends the horse whose hoof is, at any time of life, near 45 degrees of elevation or depression. Did we require more arguments to prove this to be the proper elevation, a conclusive one could be found in the well-known circumstance of those hoofs of horses which are very upright in early life becoming the lowest when the animals get old; whilst those hoofs which come near the standard of excellence in youth (45 degrees), retain the same form, as nearly as the injuries of shoeing admit of, to an extreme old age*.

* Contrary statements have been made by writers deserving our respect, as to ugly hoofs remaining free from disease; but then, these were strong hoofs, though distorted, and the owners had sense enough to keep their horses in general bodily good health, so that the evils of distortion were not further aggravated by the disorders of the system—as we have shewn happens in all such derangements. Much cause for curious reflection might be found in the agreement of the proper elevation, with the annexed conic section of a semidiameter, to which we have extended our diagram, fig. 5.
Reader,

10. So far as the foregoing observations on the fore legs apply, they do belong, in every particular, and with equal reason, to the hind legs also; with the exception, however, of what is said concerning the elbow of the fore leg, and its adhesion to the chest, for which we must now substitute the stifle of the hind leg [N. 30]; and add, instead of the kind of defect described as being occasioned by the contraction of the part, it is here owing to the expansion or spreading of the stifle from the sides. This throws the houghs together, and forms "cat-hammed horses," as they are termed; the mode of going such animals are constrained to adopt, the circle their hind feet describe at every step they take, the additional fatigue they undergo, the awkwardness of their tread, and the consequent diseases communicated to the sole, lately described (in sec. 6.) as pertaining to the fore limb,—most undoubtedly afflict the hind limb also, with the additional fact, that this one is more liable to "grease." At rest, if an animal so built does not place one foot before the other, his houghs not unfrequently touch each other,—poneys and low horses more particularly so; and it seems worthy of remark, that this species of malconformation never appears on the fore and hind legs of the same animal. Indeed, we cannot recollect having seen one instance, and we are thence led to conclude that this twist of the legs is a contrivance of Nature to accommodate itself to
the disproportionate length of legs before or behind (see fig. 6.) But, when it so happens that the strength of the parts resists this bending of the hough or of the knee, such horses walk higher behind than before, and *vice versa*; *i. e.* when one pair of legs seem to have outgrown the other pair, a defect which, though often overlooked, is no less deserving of notice,—the wound termed "overreach" is inflicted by the hind leg of this formation upon the fore one. "Forging" is, likewise, occasioned by the hinder toes striking the shoe or shoes of the fore feet; and is sometimes brought on by injudicious shoeing on feet of the very best construction, and a *loose rein*; it is, therefore, to be corrected only by the contrary practice, keeping the hind toes short, and the heel of the fore foot low, and riding with the reins borne up. By those means, the fore hoof will spread at the heel, and the animal be enabled to take it out of the way in time for the hind foot to occupy the identical spot on the ground it had just quitted; for very few horses have the *greyhound-tread* of Eclipse before noticed, wherein the hind feet tread much wider than the fore feet. Neither is such a gift desirable to any but racers, perhaps; nor is it,
indeed, compatible with the duties the generality of horses have to perform.

The great additional labour horses with houghs so formed undergo, added to the pain and anguish of continuing it, occasions irritation of the whole hind quarter, that communicates itself to the region of the kidneys and intestines, and superinduce inflammatory complaints, which frequently terminate unfavourably. *Constitutional diseases* appear on the leg behind oftener than before; and those of the coronet, with curb, thorough pin, spavin, strains, windgall, scarcely fill up the catalogue of evils caused by, or receiving aggravation from, too much expansion of the stifle, with its attendant, the cat-hammed hough, and, consequently, a twisted tread of the hoof. No doubt exists in our mind that Eclipse would have been a cat-hammed horse had he been raced at two or three years old, as our practice now is: but both he and Flying Childers were five years old before they started on the turf. Heavy long-legged children of our species, in like manner, become knock-kneed men, by being put on their legs too soon; this form of their knees deprives them of calves to thin ill-formed legs, and the thigh, too, seems wasted, when the deformity is great; as it does also when they wear unyielding clod-hopper boots, or shoes shod with iron. Whereas, our Welch, Cornish and Irish peasantry, who run bare-footed in early life, can boast enormous calves—the Cornish in particular.

11. When the *fore legs* are shortest, the horse,
whilst going, nods his head up and down a good deal, as he does when these are either weak, tired, or tender of foot: when they are very feeble, without other ailment, he carries the head high constantly; but he works his head from side to side when the same subjects of complaint assail the hind legs and feet and carries low. Poneys being ever out of point in one or the other of these respects, afford unerring proofs of those remarks. The value and advantage of the straight position of a horse's houghs are never more apparent than when he rises upon his haunches to take a leap, a service which never was performed satisfactorily by a cat-hammed horse; because he seems to hesitate about what shall be the distance between his feet at the precise moment they are to leave the ground; a blunder which is most visible in the standing leap, when the feet are seen first to straddle to their utmost; in an instant they are brought so close together as to lose all purchase, and he goes over from an intermediate spot, the whole transaction occupying as much time as does the counting of one, two, three, and away!

The motions of the head are always good indications of pleasure as well as pain. A horse will frequently throw up his head, almost in his rider's face (as if to rebuke his barbarity,) when he has been hit on the head, ears, neck, or poll. (See Section 16.) He looks at his flanks dolorously when affected by a dull pain in the intestines; if it be sharp pain, he turns about quicker; he
thrusts his nose towards his chest, when pain assails his lungs generally; but when one lobe only is affected, he turns his head only to that side. If a horse be girthed too tight he will sometimes (justly) bite his tormentor, for this operation retards the action of the muscles between the ribs and of the ribs themselves, so that the lungs do not get room to play. (See Section 31.) Old horses contrive to avoid this punishment by "holding their wind," (i. e. keeping the lungs filled) during the girding; a fine proof this of Nature's dealings, for which they usually either get kicked under the belly, or hit about the head; but both kinds of punishment are the harbingers of further disease, viz. the first of the blind gut, as described at Sections 48, 49; and the other leads to poll evil.

A horse is frequently found to have contracted lameness in the fore leg without showing any visible sign of its exact situation, and applications, of the oils to the shoulder is the usual remedy in the hands of the generality of common farriers. Some of them imagine the strain is situated lower in the leg; but they are no nearer the fact, though they are to the spot. A defect in the conformation of the limbs occasions the foot which leads to come upon the ground with more force than its fellow; the concussion of the hoof is greater, and is unequally placed when the leg is a-twist than in the upright form; the leading leg tires sooner, and the sensible sole becomes inflamed when the horse is constantly urged to step out with it, the affliction
barely showing itself between the frog and the toe, if any where. If a horse receives the impulse to proceed from the right hand or heel, he will step out with the fore leg of that side, accompanied by the hind leg of the near side; but his rider, or driver, should early teach him to change the leading-leg, by sometimes touching him up on the contrary side. It is worthy of note, too, that the horse which executes this change with the least trouble, and oftenest, has most power and command of his limbs. [See Index—Fever in the feet and Strains.] When both legs before are attacked, the horse exhibits a crippling uncertain gait, not unlike that of a drunken man, whence the term "groggy" has been applied (in Yorkshire pronounced "graw-gy"); and, if he is not timely indulged in rest and a run at grass, he is a ruined horse, and becomes soon what is termed "foundered," of which disorder there are several kinds. The mistaking one kind of founder for another generally costs the animal his life, sooner or later, and the studious inquirer had better turn to the next Chapter (at sect. 21, paragraph 3,) where he will find a few words on chest founder, many of the symptoms whereof are not unlike this of the feet, and proceed from the like causes.

Horses full of feed, and requiring purgative physic, stand with the legs stretched, more than our second cut at page 30,—inordinately at times. Old Gibson attributed it to vice, and a disposition to kick, when a horse holds his toe scarcely
resting on the ground; this is not always the case, for his fore leg is as frequently held a-trip as his hind one; and we consider it the token alike of sore foot, of tiresomeness, and of incipient founder.

12. Besides the disproportion the fore and hind legs bear to each other, another series of defects in construction exists between the length of the fore limbs and that of the trunk, being sometimes most apparent at the belly and flank, at others on the back, its tendency always depending on the turn taken by the latter. Although this is the old English way of judging of long carcased horses, Lafosse took the measure of proportions more properly from the breast-bone to the buttock, being in the annexed plate from the parallel line 11 to 38; then comparing this with his height, he tells us “a good horse, as we can learn from experience, should be a tenth longer from the breast to the buttock than he is high from the top of the shoulder to the ground.” The latter admeasurement will be found upon the annexed plate to extend from the line [E to Z] and, with the former, will compose a square rather wider than high,—the integuments being removed from the bones on all sides.

Our notions of just proportion, however, differ from the French standard, though they do not run into the contrary extreme; for we cannot help thinking inordinate length of body, as compared to a horse’s height, a very great defect as regards his health, that form being invariably attended with meagre, washy flanks, and a painful manner of going. But
the Flanders and Norman breeds have all this tendency; and they are invariably of a sluggish nature, when the belly, also, hangs low.

The major part of our horses of this built have their sides falling in, more or less, toward the hind quarter, some few of them to such a degree that the flank appears as if it were fastened to the loins, These are remarkably poor feeders, have a good deal of short-lived vigour, without the gift of keeping it up at any kind of thing. Nutritious food, but less in quantity, does for horses which are out in the first-mentioned point all that can be done, and that is very little: those of the second species of bad form cannot bear long journeys, nor long privation, or they are liable to contract flatulencies and spasmodic cholic.

Another species of disproportionate length, as compared to height, consists in what is called "high-mounted," the limbs having then much more length than the body; a defect that is rendered still more apparent when (as generally happens) the horse is also roach-backed, like the first sketch of back-bone in the next page; and it is still more striking when a little man is mounted upon it, with a saddle that is ever sliding forward upon the withers. Such a form always denotes weakness of limb, and want of freedom in the forehand; nor can a horse of this built take a long step, nor trot well, nor thrive in the field, by reason of the difficulty he has in reaching the grass, which induces him to bend one knee forward, whilst the other leg
is drawn back under him. Foals have all the appearance of being high mounted or high behind, until the filling up takes place, and they settle into the proper shape: such become speedy horses.

13. But a horse may be short in the carcase, which is not exactly "high-mounted," in our view of the term; since much will depend upon the shape (or bend) of his back-bone, to bring him under the one or the other description. We have seen what sort of character a roach back bestows on a horse; the direct contrary form, or hollow back-bone, [see the lowermost sketch (c.) in the margin] is no better, though built upon long limbs, horses with this shape back being in all cases weak in the loins; and, therefore, they are more liable to contract inflammation of the kidneys, and to resist
the cure longer than those of any other shape back whatever. Yet are they preferred by timid horsemen, principally on account of the easy seat a hollow back affords. Great caution in administering strong repeated diuretics should be impressed upon our minds at the sight of a very hollow-backed patient. See Sections 53—56.

When the bend in the back-bone, or "hollow back," is restricted to the fore part of the animal, the loins being well filled up, his built in other respects is less material, to be "short in the carcase" being then an advantage; and it is much greater when the said bend is confined to a gentle curve, scarcely distinguishable, just behind the withers. [See the middle sketch (b.) in the last cut.] This is considered a straight back, belonging to a tight made, compact horse; he is invariably ribbed home: and, as there then exists but a small space between the last rib and the hip-bone, as seen in the plate at 30—34, so is it always accompanied by the deep chest, good hind quarters, and wide loins (i. e. not pinched together,) and his ribs finely curved. Horses so formed are always healthy, and esteemed, at first sight, superexcellent, being supposed, with justice, capable of doing more work than those of any other built whatever. But the gift of leaping, or of great speed, do not always belong to horses of this form, however perfect in other respects, though health, vigour, strength, and lastingness do. Such horses always feed well and retain their condition. The inquiring reader would
do right to turn back to what is said under Sect. 10, and draw his conclusions from the nice distinction.

14. Low-buttocks generally accompany roach-back, [see sketch (a.) fig. 7.] Roached-back is brought on by putting young horses to heavy draught too early in life—ere the coverings of the bones (See Section 16.) are sufficiently braced, and are always attended with another fault,—"hind legs too straight," and incapable of stepping out. A horse so formed can execute no pace tolerably, and trotting worst of all. In the drag, such a horse steps short, and is always upon the bustle, as if his legs were tied. A large head, also, with short thick neck, denotes him a sluggish horse, heavy in the hand, and usually "carrying low:" these are faults generally attending his entire breed. When the neck is longer, the case is not bettered, for then the animal is of the long-bellied kind, with thin flanks and washy. All large heads are attended with thick fleshy legs, much disposed to grease: and as a small light head, but wide at the forehead, with expanding nostrils, and bold prominent eyes, denote (blood) strength of body, and vigour of constitution, so the contrary may be looked for in horses which have narrow foreheads, small or sunken eyes, and small arid nostrils. I never saw a fine well-turned head that did not belong to a good set of legs, well fixed upon the body; this correspondence of head and heels goes still further, inasmuch as the quantity of white in the face is commonly attended with a proportion of white upon
the heels, thus: a *star*, one white foot; a *blaze*, two white feet; *white face*, four white legs, &c. Horses with *large jaws* are given to keep open their mouths while at work; and, when aged, grind their teeth more than is necessary in feeding. The manner of breaking his food being, with the horse, different from that of other animals, viz. by rubbing his under teeth *from right to left* against the upper ones,—a motion to which the term "grinding his corn" has been applied;—an old horse will sometimes contine it when he has nothing to eat, thereby wearing away his teeth; a circumstance that occasions imperfect mastication, and its consequences, besides subsequently leading us into error in examining this test of his age. *Hard-mouthed* horses, and those which champ the bit much, fall into this idle habit.

**Flat,** or *narrow-chested* horses are subject to those attacks which lead to *consumption* (see sect. 36), and, consequently, are liable to show *bad condition*; or, it may be, that disorders of the chest do contract its *capacity:* as horses that die after long-suffering in the lungs, and parts adjacent, as I mean to show in a subsequent page of this volume, have the internal part of the *breast-bone* much affected, as if the moisture thereof were dried up by the heat of the contiguous disorder. In some horses, on the contrary, the cavity of the chest seems too great for its contents; they are "broken winded" horses of one description, (there being several) that are afflicted with these kinds of mal-
conformation, or disagreement in size between the parts containing and those contained.

15. Now, reader, our purpose in making this exposition of the ill-effects produced by mis-shapen limbs, &c. on the horse's health and usefulness, would be incomplete, were the original causes thereof left unnoticed. The most remote, or more general one, resides in the breed, or the manner of breeding the animal, whence we are sometimes led to say, "What is bred in the bone will never go out of the flesh." As regards the kind of stock from which to raise a supply of young ones, breeders may undoubtedly suit their own fancies; but it must be seen that a brood mare which receives too much of the horse for her capacity will produce a foal all father, as it is called, being at the same time larger than she can conveniently carry; it then bids fair from the beginning to be a mis-shapen animal. This happens oftener than is commonly imagined; but it is easily prevented by adopting a horse for her whose strength comes tolerably near that of the mare. Disregard of this precaution is found to produce the first foal much smaller, though more lively, than the next and subsequent ones, especially if care be taken in the latter case to give her a horse more and more vigorous as she becomes more roomy. For it must be clear to any body [upon mechanical principles again] that if the foetus, growing too large for the cavity in which it is generated, originates too much bone, it must determine towards some particular
part of the young animal; and the colt will be brought forth with that deformity, and carry it through life to the knackers, after plaguing two or three of its owners with fruitless endeavours to physic off its ills.

We say nothing whatever of the cross to be adopted; that being withoutside our plan, would carry us too far away from our main subject. But we may observe, in passing on, that no breeder in his senses would think of employing a horse to raise stock that has served half a dozen, or more, mares in the course of the day; and yet nothing is more common, nor more inevitable, when the payment for covering is low (say a guinea or two), than that the smallness of the sum must be made up by the number of mares served, the price, keep, and attendance upon stallions, being expensive. This error must be so palpable to any man who calls himself a father, as to render any further argument upon that topic utterly unnecessary. Some twenty-five years back into the last century, we recollect reading a well-attested account of a celebrated horse’s dying in consequence of twelve or fourteen successive efforts in procreation; and if such be the deplorable case with the parent, what strength, bottom, or lastingness, can be hoped for in the progeny so begotten? Nevertheless, we are of opinion, that a vigorous horse, which may have been freely engaged (if early in the season) may be in a better condition for raising large and lively stock, than under any other circumstances whatever, except
recent exhaustion. Aged stallions produce hard-mouthed foals, and further proclaim the ill-adapted ages of sire and dam by extraordinary hollowness over the eyes.

Much depends on the country, the climate, or kind of land, in which the gestation or breeding may be carried on; and it may be presumed, that no one in his senses would choose such a situation as is known to be disadvantageous to the particular kind of breeding he may have in contemplation to pursue: whilst those who may already be so placed, have no right to complain when they engage in a branch of business thus ill adapted to their plan of farming, and they get disappointed. As both objections lie at the option of the parties concerned, they require no farther remark; but another point of consideration well worthy our careful attention is, the treatment the mare ought to experience at our hands while she is breeding; this being a matter of some moment, and within every one’s control, should not be neglected. Though a brood mare in foal requires no pampering at any period, yet is it clear that, from the third or fourth month, she should not be worked so hard as usual, and from this period to the day of her foaling, the duty to be required of her should be less and less every week. Nor, on the other hand, is complete idleness befitting her situation: in cases where she has not been used to hard labour, a run at grass, in a paddock, with access to an out-house or stable, as it leaves to her option the quantity of exercise her
strength is capable of sustaining, would be found most conducive to the best purposes of nature. Her food should be of the first quality, and regular, and, though full enough, need not be too much. Occasionally, she may be off her feed, during the "time," but she does not therefore require "physicking," nor coaxing to eat. Great care should be taken that her body is emptied regularly, that no derangement take place either way; and that if opening physic is required at all, a strong dose of aloes is not in her case the best that can be prescribed for that purpose, since they act mostly upon the intestines lying immediately in the vicinity of the foal. An opening draught or drench should be substituted for the pill, as its operation begins sooner *.

A very general cause of mis-shapen limbs is the placing upon younkers too great weights at first mounting, whereby the houghs or the knees are thrown together, particularly, when the animal is constructed with the fore and hind legs disproportioned to each other, as noticed at sections 9 and 10. Splents and sprains are the inevitable consequences of mounting colts, &c. too early in life; and hollow-back is oftener induced by this premature

* Or, let the pill be divided into two or more parts, as spoken of much at large in our "Grooms' Oracle," under the articles Physic and Aloes. Here humanity shudders to think what destruction has been dealt over the land by the two extensively spread impostures necessarily castigated at page 2; happily for the third mentioned, however, his volumes are innocent of extended sale. White knocked them on the head.
error than existing originally. As if all this were 
not enough, many breeders nearly starve their 
young ones until they are brought into use; whereby 
they become deficient in solidity of bone and quantity of muscle, if they do not imbib[e] some internal 
or constitutional malady, and the event of their 
limbs growing mis-shapen is no longer left to change.

16. Notwithstanding all that has been said and 
done, little would avail the finest proportions of 
the bones towards the formation of fine-shaped 
limbs, least of all to symmetry of the whole horse, 
but for the seemingly adventitious circumstance 
of the covering with which they are immediately 
invested; and which, embracing tightly several 
bones, and connecting them together, constitutes 
a limb. Some of these coverings are confined to 
the joints only, holding them in position as near 
as the Creator designed them, unless accident (of 
parentage, of birth, or mis-usage), as before de- 
scribed, should induce them to a perpetual strain, 
and they enlarge at these joints in spite of the next 
or universal covering of the bones: this is mem-
brane (of which more shortly), the uses whereof on 
the bone may be illustrated by taking a stocking 
of good length, and having filled it with pebbles of 
its own size, and tying the end tightly, a stick or 
club is produced of some degree of flexibility, re-
sembling a limb and its joints. If the tying be not 
performed well, by bracing the stocking to its ut-
most, the flexibility of certain parts (or joints) of the
limb will be greater: it will possess less strength at the joints when bent, and be liable to give way or break unless supported by some other covering. The form or style of going, is frequently affected by the relaxation of this universal covering of the bones, always with young horses, not yet arrived to a sufficient age for being well braced; some breeds are naturally loose built in this respect, and many otherwise good horses become relaxed through age, hard usage, a humid climate, over physicking, or a cold in the limbs. Perhaps the knee-pan is that bone which depends mostly upon being kept in position by the immediate covering thereof, having decidedly no muscular covering; yet I have seen a case of the knee-pan being displaced and replaced several times, no one being aware of the cause of the original displacement, further than this general conclusion of ours. It is easy to perceive that the horse which has those coverings in the highest perfection would move his limbs more correctly after the fashion they were designed for, than he which constantly strained them out of their places. He who was endowed with the first-mentioned quality in perfection would be considered a sinewy tight-built horse; the second kind we have already depicted in section 10, where the houghs are described as keeping those integuments in a perpetual state of derangement, straining or twisting them in such a manner, that constitutional enlargement at the joint is the natural consequence.
At the ends of all bones, a yielding substance, in appearance like bone itself, prevents friction, and by its elasticity gives a spring to the animal's steps. The ease of a horse's going mainly depends upon this substance, which receives the name of cartilage, and is liable in some measure to be absorbed or taken up into the system, or, in cases of diseased joint, to become stiff and bony. Consult section 23, &c. on those points of information. We may notice this absorption in very young animals, whose bones are all substituted by cartilage, until the blood furnisheth the means of forming a more substantial frame, such as we have been describing; and teaches the validity of some remarks I made in a preceding section (15) on the kind of attention we ought to pay to our brood mares while the foetus, or unborn animal, is being formed in the womb.

Not only between bones, and embracing every joint, but at the termination of the four legs in their horny feet, is this springy substance to be found, the whole being liable to wear out, to contract or to harden with age or disease; whereby all old animals appear shorter than those in the vigour of youth, and horses more particularly are liable to contract a stiffness of the limbs, and a rigidity of the whole frame, that at its last stage is termed "lock jaw." Besides this casing of the joints in cartilage, the ligaments connect or tie the bones together. These ligaments are seldom troubled with any ailment but that of great lassitude.
when the animal is tired, and occasionally to sprain. This accident takes place when the horse steps aside upon uneven ground, and the ends of the bones press laterally upon the ligaments. It follows, of course, that mis-shapen horses, whose feet are always constrained to take an uneven tread, must be subject to a constant strain, and must be more liable than others to incur permanent accident,—every step forming a trivial one.

But the ligament demanding the student's most serious attention is that which suspends the neck bones, on the same principle as our old-fashioned lamp-irons are suspended by a small one from above, only that the ligament lies closer, and covers the bones on the upper side, as at a—b of the annexed sketch. It is called "cervical ligament." In operations for the poll-evil this ligament is frequently divided by the unskilful farrier cutting it across rather than lengthwise, which is the only right practice. So placed, and passing from the skull (at 4.) to the blade bones, to both of which it is fastened, it has the power—at the will of the animal, of bending down or drawing up the head, which would, in fact, but for this support, fall to the ground. Horses in their last moments, when that will may be supposed to have left them, always cast back their heads considerably, by reason of the contraction of this strong ligament during the paroxysms of departing life. At a, however,
where is the seat of poll-evil, it is usually thin, the cavity there found between the bones being mostly filled with muscle (section 27.); but this does not happen invariably, as some horses have little or no cavity to be filled with ligamentary substance, or with muscle. Our frontispiece is the portrait of a subject of this latter kind: but the reader is referred to some subsequent observations and cases on "poll-evil" for more detail on this hitherto-neglected point of conformation.

17. At the joints formed by the bones and covered by cartilage, the whole are surrounded by a strong membrane, which wraps the bones tightly, and secretes an oil at the joint for its further defence from the effects of friction. Of this secretion, and of the membranes generally, some further notice is taken in the second chapter, at section 22; its absence constitutes Anchylous, or stiff joint.

This strong membrane is not, however, confined to any particular part, but continues its close attachment, or embracement of the bone, over the entire frame of the horse, from the crown of his head to the soles of his feet; at the latter parts protecting and further defending them from the harder substance with which they are surrounded. Throughout its extended course it serves as an excellent holdfast for the sinewy ends of the muscles (see section 27.) which are attached to it above and below joints, whereby they act as levers to raise the lower bones of the limbs, as described hereafter.
According to the parts this membrane may cover, it has received from the learned, in hard words and many, a separate name for each, as if that course would further the cause of science; and whenever they speak of it as being found upon the joints, the skull, or the bones generally, they term it perichondrium, pericranium, and periosteum, as the case may be: why, no one explains. It has been considered insensible, because in health it has not the sense of feeling so fine as other parts of the system, which are furnished with more nerves (section 30.); but the very few of these fine organs with which the membrane of the bone is furnished, renders the pain occasioned by disease, whenever it may be attacked, the more acute; when flying from one nerve to another, those well-known shooting pains are felt (by us) that are universally mistaken for pains in the bones themselves. We do not go too far in inferring that the horse is similarly affected. This takes place in splents and spavin, when the bone enlarging forces its way through this tightly-braced membrane, and causes inflammation, temporary lameness, and, at length, those well-known appearances we have just named. In the living horse this membrane is red, by reason of the fine blood-vessels with which it abounds; but in the dead subject, the supply of blood being withdrawn, it then turns white. The chronic pain we term Rheumatism, resides in this membrane.
CHAPTER II.

Concerning the Horse's inside, of its conformation, the functions of the organs of life, and the diseases to which each is liable; together with outlines of the principles upon which the cure is to be effected.

18. Such, dear Reader, as we have endeavoured to teach, being our view of the external frame or structure of the horse, which we have termed his built, we come, in the next place, to speak in a more particular manner of his inside; noticing, as we pass on from one part of him to another, the seats and causes of his diseases, with a view to their cure, but referring you to the second book for the separate treatment each requires. In the next chapter will be found our reasons for following up the principles herein laid down, by a line of practice, at variance, in some material points, with the present mode of treating the animal in health as well as in disease.

Organs.—But, before we proceed to describe those several parts of the horse's inside, there appears to us an absolute necessity for previously bringing the unlearned reader better acquainted with a few general topics, that we may proceed with the details smoothly and more intelligibly
together; *viz.* the names, uses or *offices*, and powers, of that infinity of *small organs* which lie spread over most parts of the body, and belong in common to several of these *parts* in nearly an equal degree. The *large organs*, having the main power of carrying on the animal system, *first* as regards *digestion*, *secondly*, those employed in the *circulation* of the blood, and, *thirdly*, those of *respiration*, are too well known to the sight and touch to require explanation here; yet are they (the heart, kidneys, *lungs*, or lights, liver, &c.) composed or made up entirely of those *minor* organs we mean first to describe. But the precise way in which these act in and upon the large ones, the great share they hold in furthering the system of animal life, and the eminent rank their services maintain in restoring health when the system is any way disordered, has not received, in the practice of horse-medicine, that share of serious consideration the importance of the subject imperiously demands. To these points, then, we shall shortly call the reader’s undivided attention; mean time, as some hard words and cramp phrases are applied by most people (writers and others) to those *offices* or functions of the animal’s organs, they stand in need of previous explanation.

19. Each kind of organ, whether small or large, was designed by the great Maker of all things to perform some office towards the preservation of the animal in health. When such office is performed properly, as ordained, the organ is said to *"per-
form its functions well.” For example, the heart is given for the purpose of sending the blood through the arteries, all over the body; but when the pulse beats low or irregularly, that organ is said to “perform its function badly;” when it ceases to beat, this function is lost or gone. So, certain of the organs are said to secrete something or other that is liquid; the doing this is their function; the power of doing so, that of secretion, and the article secreted or collected together, is called the secretion of this or that organ. Thus, the kidneys secrete urine, and it runs off (sect. 53.); the glands, under the jaws, secrete spittle (saliva), which passes off with the food by the intestines: therefore are they properly considered as excretory also, seeing both the secretions are drawn together for the express purpose of being so sent away, this last by the grand canal (or gut), as the first-mentioned is by the bladder, and the perspiration is through the pores of the skin. But some secretions are found that have no outlet visible to us weak mortals, though they find their way through the skin, sensibly enough at times; and this then becomes the sensible perspiration or sweat, but when we do not see it, this third species of evacuation is termed the insensitive perspiration; and, in health, one of the two is always in action,—in disease not so: we then give sweats, or procure them by exercise.

When, however, it happens, such functions are obstructed, or, on the other hand, too much of either secretion is furnished to the system, then disease
begins; as does, also, our duty of finding out what part of the vast machine has ceased to perform its office properly. For, without this previous information, no man can possibly know how to apply the remedy in restoring the disordered organ to the proper exercise of its function; nor can any one hope to arrive at this desirable point of veterinary knowledge, unless he has acquired the means of ascertaining where, when, and in what degree the mischief has taken place, by patiently examining the action of those organs while in health, and comparing their appearance, after death, with the particular symptoms which preceded that event.

20. Secretion.—Although, as we say, the secretions just spoken of are important in themselves, and of several sorts, as bile or gall by the liver, urine by the kidneys, &c. yet the chief object of our present notice is the secretion of a fluid, more or less watery, which pervades the whole system. It differs in quality a little, and very little anywhere, being adapted to the nature of the parts requiring its aid:—1st, In softening and enabling them to move freely over each other (as, between the ends of bones); 2d, Acting as a defence against injuries from extraneous bodies (as, on the inner coat of the intestines); and, 3d, To prevent the parts from growing together; as the liver to the midriff, &c. Misfortunes these which invariably happen when the supply of this fluid falls short of the requisite quantity for a long while together; and this is the case whenever the animal is worked
until the fluid, at some part or other, is exhausted; a circumstance that strongly bespeaks the propriety of allowing the worn-up poor creature more frequent supplies of water, although this be done in smaller quantities. Inflammation, or fever, which is occasioned by suddenly checking the secretion, eventually exhausts this moisture by its great heat. Both these disorders are, therefore, referred in the sequel to the same origin; the first being local, or pertaining to some particular organ or part, whilst fever pervades the whole system, and the solids in particular. The total absence of perspirable matter marks both diseases.

On the other hand, when too much of this fluid is secreted, and remains unabsorbed, other diseases ensue: upon the heart it forms "dropsy of the heart-bag;" on the covering of the lungs it becomes "dropsy of the chest;" in the membrane of the belly it forms (ascites,) or dropsy of that part, and usually falls into the scrotum. The powers of medicine have hitherto proved of no avail in the first description of ailments; and are but partially applicable to the last mentioned: the operation of tapping too frequently disappoints our hopes, to induce us to rely upon it as any other than a temporary relief, and it is, therefore, seldom or ever applied to the horse. Thus, in whichever way we view this important secretion, its eminence must strike us as quite equal to any other. Whenever obstruction in this part of the system takes place in the horse, the consequent adhesion of the parts
being invisible, he gets worse used by his inexorable master for his inability to perform his usual work, and he soon falls a victim to the lash, the spur, and the bit. At the joints, this fluid is considered to be an oil (synovia); at the heart it is confessedly nothing but water; whilst it partakes of a mucous, unctuous, or slimy nature at some other parts of the body. This is the case with the membranes of the throat and gullet; on those of the nostrils, the heat of the horse's breath converts it into a "viscid mucus:" when the secreted watery particles come off by sweating, it assumes a white or milky appearance, after a little time appearing thicker and more slimy as the sweating continues, and the watery particles becoming less and less, its fluidity is also lessened. See Membranes, sect. 26.

21. In all animals, the secretion of this watery fluid is carried on by the membranes, which are thin films placed between the various organs, over the bones and among the fleshy parts. These not only secrete, but sustain the fluid in its place, for the purposes above mentioned, and being of various texture or fineness, the fluid that is so secreted and held to its purpose by each, partakes more or less of water, is more or less slimy, or consists more or less of an oily nature, according to the use it may be designed for. Each kind of membrane and its proper secretion, has received a learned name,—the first being called serous, the second mucous, the third fibrous; but, having resolved to abandon learned words, whenever the thing...
can be understood as well without them, we find less occasion for introducing them here than is generally practised. For, the peculiar nature of the horse having assimilated together, by its action, the three kinds of secretion more so than is the case with other animals; and his habits contributing as much more to the hasty calling off of one kind of fluid from certain parts to the assistance of another part, which may have been exhausted of its kind; and as the treatment of the horse in all cases of a disordered secretion of these fluids is the same throughout, the action of medicine upon one always affording assistance to another (as we shall prove shortly), there is no such necessity for carrying the distinction farther in horse-medicine, although it may be very proper in the human practice.

Perspiration is always at a great height in the horse; it is one of the chief means of cure in most of his disorders, and consists in drawing the watery secretions from all parts of the body. These pass to the surface readily, coming through the membranes from the joints, the solids, and even the bowels and their coverings: as may be noticed in the case of hide-bound, upon opening the animals that die in this state of exhausted nature, the mesenteric canal (hereafter described) is invariably discoloured with yellowness, being, at times, nearly orange colour; but we have almost as constantly found the lacteals of a fine-coated horse shine through as white as milk. Again, on over-working the horse, so much
of the joint-oil is sometimes drawn off by perspiration, that he becomes stiff in the knees, for want of that softening quality which kept the parts supple: we feel the same ourselves upon such occasions; and, in taking off the knee or the hough of a permanently "stiff-jointed" horse, we have invariably found the joint-oil affected; in very bad cases it no longer existed. During life, the escape of this oil, by reason of wounds, (as bad broken knees), leaves the joint stiff. Further comment on its uses is unnecessary; but these facts should teach his owners a practical lesson of moderation.

On the subject of absorption of these secretions, we noticed, many years ago, a very ingenious reason assigned for "lameness of the fore legs, of English horses particularly," in the great work of La Fosse, the elder, on what he calls "Hippopathology," or the diseases of horses. He says, "The fluids which hitherto lubricated the parts (the shoulders) and kept them supple, being reduced in quantity, the fluid flying off by sweat, the remainder gets thicker in consequence, and the solids of his limbs become stiff and dry." It happens mostly in the fore limbs, and he calls it a cold or chill, and says, page 267, it resembles a "stroke of the shoulder,"—"Cheval froid et pris dans les epaules." A species of founder, that is clearly not to be cured by external applications, (as the oils, firing, &c.) but by restoring to the part the function of secreting a sufficient supply of the fluid which had been so exhausted. In these few words are
included the whole secret of my method of cure in such attacks; and, in this case, gentle sweating is that remedy which is best calculated for restoring the function.

22. When the skin does not permit evaporation, and send forth the secretion by perspiration, disease has begun, the hair looks staring near the part affected, and not a stable-boy exists, who, when he sees a horse with a rough coat, cannot tell that "something or other is the matter with him." This arises from want of moisture within; the skin itself not having the power of secreting or drawing towards it, by effusion, the moisture which is necessary to keep it supple, it shrivels up, and this important evacuation, which is second only to the urinary, is then stopped, so that even the insensible perspiration ceases. Some idea respecting the amount of this insensible evacuation may be formed by placing a horse, that has been exercised, between ourselves and a well white-washed wall upon which the sun shines; when the shadow of the insensible perspiration may be seen upon the wall ascending in tolerably thick volumes, something very like steam from a boiling pot. Indeed, the insensible perspiration is, when compared to sweating, the same as warm water compared to boiling water.

Yet, although we do not know the exact workings by which this internal effusion (as it is called) of the watery particles from one part of the animal to another takes place, we do know, accurately
enough for our purpose, that abundantly perspirable matter lies in and upon the intestines; as any affection of the heart, arising from the organs of sense (sect. 30.), causes a sudden effusion of blood in the skin, and induces heat and irritation there. Fear, for instance, of the dealer's whip often occasions the skin to contract and expand, so as to cause the tail to shake with every alternate vibration of the heart. In like manner do the intestines send forth their watery particles, upon the slightest occasion, to the same place of exit, in order to moisten and render it more supple. Whether the very transparent membrane, called peritoneum, which sustains the bowels, or that other large part of it which covers these and all parts of the inside, is most concerned in this secretion and effusion, is not worth the trouble of inquiry here. But in addition to what is said in the last section respecting the colour of the lacteal duct, as it passes along the mesentery in case of hide-bound, we may be allowed to observe, that we may daily prove that the sensible perspiration from young and healthy horses contains more of water than is found in feverish, old, or generally unhealthy animals; and that, with these the sweat is more frothy, or becomes so much sooner, the mouth getting clammy, and the tongue dry and hot underneath, with less work than younger ones; and that horses so affected are always found insatiably craving after water to supply the waste that is constantly going on. Moreover, as regards the connection that subsists between one
part of the animal and another, we have many times found purging physic, given in the usual dose, fail of the effect intended, and come off in the shape of profuse perspiration. Not only in those large and decided doses, that are intended to produce much effect, but milder ones also, as alterative-laxatives, often turn out of their course, and, as well as diuretics, not unfrequently disappoint us in the same way, the latter also coming off by the skin instead of urine; which is, besides, a very well-known natural operation, usually described by a vulgar saying, "The more you sweat the less you'll p—-." Tears, or any other evacuation of the water that moistens the animal system, are liable to the same kind of comparative remark. When excessive salivary secretion attends the tooth-ache, the glands of the mouth and jaws carry off so much water as to affect the quantity of urine voided, and we may infer that a diuretic would reduce the inflammation of the jaws. It follows, of course, that the less sweating a horse has got, the more he must stale, and accounts for the profusion of the latter kind of evacuation in winter, when he scarcely ever sweats, and perspires but little, comparatively speaking. As a farther proof of this connexion between the secretions and evacuations, let any one notice a horse when he first stales in consequence of taking a diuretic, and he will find a transparent water hanging in little globules at the end of each particular hair of his coat, all over his carcass.
23. Reader, we come now to speak of glands, nerves, membranes, absorbents (being 1st. lymphatic, 2d. lacteal), and muscles, which are the names writers and practitioners of eminence have agreed to give, when describing those numerous minor organs that are employed throughout in carrying on the functions of animal life, and the uses whereof we shall come shortly to explain. The reader is already aware of the sinews, of three kinds, that more immediately cover the bones and keep them in their places (sect. 16, 17.), to which, if we add the bare mention of the muscular, or fleshy parts, and refer to the "circulation of the blood" (sect. 37—44.) for a description of the veins and arteries, he will have before him the names of all the integuments of a horse's body beneath the skin. Detailed particulars respecting all these follow next in their order; the larger organs of the inside being reserved to the subsequent sections of this chapter. By this course of proceeding he will be better enabled to comprehend, as we study those things together, why and wherefore these were given to the animal, and what functions each has to perform in health; or these ceasing, or being obstructed, we shall be led to consider, in the next place, what species of remedy is proper to be applied for removing such obstruction, and thereby of restoring health; for, he may rest assured, that not the least atom of matter has been conferred upon the animal form without intending that some
good and demonstrable end should be answered by its creation. In addition to all which, there are many _causes_ incessantly operating towards the simply-grand purpose of prolonging life, and of providing for the waste which is constantly going on in the animal system, that are far removed from our sight, and others almost surpassing our comprehension, but which are nevertheless known to exist by their _effects_; but, of all these several matters, more in their proper places; _one_ instance of the insufficiency of human knowledge having been already adduced in the preceding section, as regards the unknown mode in which the watery secretions penetrate to one part of the body from another, or rather say—_drawn_ thither.

24. All these important points of knowledge in the first principles of our art lie within the compass of every man's capacity, who can read; they are certainly open to his _inquiries_; and he who is constantly among horses cannot fail to learn (after studying the subject in the manner we now propose) to make himself as well acquainted with the symptoms or signs of _approaching_ diseases as the generality of veterinarians. He certainly may render himself much superior to the old, ignorant set of farriers, who were bred up in the days of stupidity that are just gone by—never to return. Let such an inquirer after knowledge bring to the task industry, patience, and good common-sense, and he may soon acquire knowledge enough of the _outlines_ of the art to be able to pronounce when a pretender
is at work, or when it is that a man of judgment and real sound learning in his art has undertaken the treatment of this valuable animal in the distressful hour of sickness. On this head we are not ashamed, after the lapse of nearly half a century, to own that we once wept over the sufferings of a sick animal which died of the medicines administered by a stubborn self-willed farrier, who could read and write, and talk, give a drench, and drink himself—nothing more: he could not think, of course could not compare one disease with another, nor mark the difference that exists betwixt two or more that are frequently and fatally mistaken for each other. And here, once for all, we cannot refrain from thus early insisting most strenuously on one point, which, therefore, we shall not have to repeat when we come to notice certain barbarous practices perpetuated by some such men, and the not unguilty practice of other physic-giving horse doctors; and this is, in short, whoever of them dares to undertake the administering of medicines to this incomparable animal without paying especial attention to the subject-matter that is handled in this chapter, commits an unpardonable act of inhumanity on his suffering patient, and of gross dishonesty towards its owner. The remedy for a disease is not always to be found in medicine; preventives never. Purgatives are not only the most obvious means of cure, but the best, the least dangerous, and those which promise in the readiest manner to dispose the most vital function to resume its wonted action; whilst
alteratives are the safest and most effectual remedy for valuable horses, and for those which cannot be spared from labour; they are indispensable in all cases of vitiated blood, and where found ineffectual nothing else can be of service. Bleeding is the very best or the very worst auxiliary we can employ; its efficacy and precise periods of utility may be learnt in the sequel, (see sect. 37—44.), where "the circulation" comes under consideration; also in the first pages of Book II., where the pulse is justly made a subject of prime consideration.

25. For the sake of being more clearly understood, we shall, when explaining the formation and functions of the horse's inside, consider it under two distinct heads; namely,

1st. The fore part, or throat part, as it is called, from its neighbourhood to the throat, or gullet, See page 98; and
2d. The hinder part of him; being his belly, properly speaking, page 128, &c.

The contents of these parts have obtained learned names; 1st. Thoracic viscera—2d. The abdominal viscera.

The fore part of a horse is that which lies between the rider's two knees, within the chest and true ribs. To the farthest of these is attached, as well as to the middle of the back bone, a natural division of the two parts, stretched tightly across his inside, like the head of a drum; and it is also fastened to his breast bone, but admits of the gullet to pass through, as it does of the great vein and great
artery which carry on the circulation of the blood of the hinder part. With these exceptions it is air-tight, and it bears resemblance to the head of a drum in another particular—it is membranous, except round the edge next to the ribs, &c. where it is found somewhat fleshy. From its situation in the middle, this natural division is termed the midriff, its edge is the skirt, and appears to have been designed for keeping back the stomach and bowels of the hinder part, which as it is, when full, press it out of shape, not unlike that of a watch glass, and would, but for this barrier, interrupt the action of the heart and lungs. But by the present contrivance, as we shall see presently, this pressure from behind soon recedes, the midriff returns to its level, and the ribs, no longer contracted towards each other by the aforesaid pressure, expand, thereby enabling the lungs to perform their function of drawing in a fresh supply of air. Upon this principal agent in the function of respiration see more detail in the 35th section.

26. After this necessary preamble, let us proceed, as before proposed, to consider the construction of

The Membranes,
Muscles,
Glands,
Absorbents (of two kinds, 1st lymphatics, and 2d lacteals),
Nerves *.

* For ligaments, cartilages, tendons, &c. see sections 16, 17. In
Of these coverings the most universally dispersed over the frame, those which occupy, defend, or embrace every part, are the membranes. As well behind as before the midriff, not only inside, but on the outside, and every part of the animal, are these skinny films placed, for the purpose, 1st, of keeping those parts which they encompass in a compact state; 2d, to secrete a fluid more or less oily for their protection (see sect. 21.); and, 3d, to prevent those parts from rubbing against and injuring each other, or adhering together. The better to accomplish these purposes, they are admirably calculated for the secretion of a fluid, as we observed before (sect. 20.); but, whenever the property of secreting such fluid is suspended, then disease begins, and according as the secretion may prevail, being either too little or too much, will be the kind and quantity of disease. Hereupon may be calculated the importance they hold in carrying on the animal system, as was said higher up.

Membranes.—To appearance they are nearly transparent, web-like, and of a strong texture; some are simply film, having more or less of feeling according to their uses, and are those which, being interposed between one organ, or part, and another, prevent the interruption which would otherwise ensue; as the midriff, for instance, which we have just above adverted to (see also sect. 31 and 35.), which is the thickest of all, or the loose membrane all surgical operations, these, with the skin, are termed the integuments, or coverings of the bones.
that covers the lungs and divides them into two parts, so as each may act separately (see sect. 32). The second species of membranes are finer, more transparent, and paler than the first-mentioned, and possess the quality of containing in their cavities, resembling sponge, the matter deposited within them by the arteries for the purpose of repairing waste and adding new flesh; these we term *cellular* membranes, from their sponge-like texture, and they are, moreover, so infinitely thin as to pervade all over the solids, or fleshy parts, without being in every case visible to the eye. They are nevertheless proved so to exist, from the circumstance of those being greatly distended, when the *subject* dies of being "blown," as we have shewn lower down (sect. 35). Then, not only the *forehand*, but the *hinder* quarter, even down to the hocks, become inflated with the wind, which by reason of the animal's being strangled, the lungs had no power to discharge, and the cellular membrane admits it into its cells, or cavities. Any one may perceive this membrane and its numerous cells to advantage in buttock of beef, or leg of mutton, after being dressed; upon taking a slice between the fingers and straining it nearly asunder, the membrane appears, but more evidently at the corners where two or more muscles meet; and in summer-time, particularly with over-driven beasts, the membrane between the muscles will be found charged with a dull brown sort of matter, that may be, and frequently is, scraped away with the knife. Another familiar
illustration of the uses of the cellular membrane, first mentioned by old Dr. Bartlett, of Windsor, in 1764, is that of "the inside of a shoulder of veal, which butchers blow up with tobacco-pipe, or quill, to delude their customers." When the animal becomes adult, or full grown, the membrane that is so capable of being blown up, is filled with strong fibrous and vascular meat, and shews the impro- priety of pushing young animals in their work before these solids have so reached maturity.

Experiment.—If one draw in his wind, and keep it longer than usual, a sense of fulness is imparted to the solids. This is no other than the cellular membrane being filled with air.

When once divided, membrane of either species never again unites as before, but in case of healed wounds the granulations of new flesh hold the divided parts of membrane to their respective places; the obstruction thus occasioned in the deposite of blood causes pain upon change of weather, when the new flesh either expands or contracts, as it may be affected by heat, cold, or by humidity. In the human physiology, another sort of distinction is made between the kinds of membrane, tending to shew whether their respective secretion partakes most of a watery, a slimy, or an oily nature; but this view of the affair is not strictly applicable to the physiology of the horse. Our reason for abandoning that course was given at section 21. We may, however, here aptly observe, regarding that species (the slimy or mucous) which lines the nostrils,
throat, and intestines, that its chief disorder is a cold, which shows itself in the cessation of the secretion; soon after this, the parts being inflamed, throw forth a thin acrid discharge, which is greatest when the inflammation arrives at its height, sometimes producing a little blood, either upwards or downwards; when the inflammation wears off, these appearances are also lowered by the mucus becoming more and more thick, until it reaches its usual consistency. The cure is to be effected by lowering the inflammation; but this is most frequently effected by the natural discharge of the mucous matter just spoken of.

27. Muscles are fleshy bodies of various sizes and shapes, according to their uses; reddish, of a grainy, fibrous texture, easily separated, but more stringy at some places than at others: the last-mentioned are termed "coarse parts" or pieces, in the animals sent for our sustenance, and are those where the greatest strength lies. These fibres formed into bundles, and surrounded by the cellular membrane, are visible to the eye, if there be not attached to each fibre a continuation of the same cellular structure that is not visible. Several of those bundles, being further enclosed by a stronger membrane, form a muscle; each whereof is attached by its two farthest extremities to some other, or, to two different bones, upon one or the other of which it acts as a lever. A muscle accomplishes this motion of the bone by expanding its belly or middle part, and contracting it towards the centre;
whereupon the bones to which the muscles' ends are so attached are drawn towards each other, and that which is farthest from the trunk is drawn forwards or backwards, at will. Thus, if we wish to bend our elbow, the muscle which is situated just above that joint, inside, contracts in length, and expands in breadth, till the fore-arm is brought up to touch the muscle itself. Fighting men (boxers) exhibit this muscle, as indicative of their strength; and horses of good action show the same sign at every movement, principally at the haunches, whilst with those that are over-fed, the muscles are concealed in fat, that obstructs their movements; whereas, with those which are impoverished, the muscles dwindle away, hang slack, and ill-support the wonted action of the bones. When much compulsory exertion, in hot weather, has exhausted the secretions that keep these parts supple, aridity, and stiffness follow, and the action becomes impeded, difficult, and uncertain.

All muscles of the limbs are long and narrow, when quiescent; those of the body are more wide than long; in a good measure, squarish, oval, or triangular, according to their uses. They have been compared, with apparent good reason, to the shape of flat fish, some being long and narrow, like the sole, others wide, like the plaice. At their ends muscles mostly terminate in a much stronger substance, closer in texture, inelastic, bending with facility, and insensible, answering the same purposes, but occupying much less room than muscle.
This substance is *tendinous*, and the horse which is well kept, having the tendons strong and vigorous, is bold, strong, and "sinewy," moves his limbs with agility, and gets over his work to admiration, by picking his feet off the ground well, and replacing them (as you can see while he is going) within a hair's breadth of the spot you may mark out for them to pitch upon. Deviations occur in certain individuals, which nature seems to have designed as a remedy for some defect or other, either of original conformation or acquired deformity. Among the latter our heavy draught cattle may be reckoned, which, after long use at the up-hill drag, invariably overstep the boundary of nature; so do better bred cattle frequently, which may be misshapen, or not built *according to the rule*, as low before, step out too far with the hind legs, and endanger forging or over-reaching; but these being wide at the haunches and narrow before (greyhound fashion) their stretch at full speed is thereby increased. Look at page 39. On the legs, tendon supplies the place of muscle, *wholly* so in blood-horses, least in the cart-horse breed. Muscle is constituted of blood deposited in the membrane, innumerable small *arteries*, some of which are invisible to the naked eye, terminating within each muscle, by a kind of doubling up, or curl, as shown in the margin; within each of these a correspondent *vein* is twined, and the whole being covered with the finest membrane constitutes a
gland. Herein it is that the veins commence their share in the work of circulating the blood afresh, as we shall see in the sequel, and the lymphatics obtain the watery particles into which the morbific matter of those solids are converted.

In blood horses (natives of hot climates), as we have seen, tendon supplies the place of muscle, or flesh, upon the limbs particularly, which are always finer than those of other breeds; this accounts why our fleshy horses in sultry weather, or hot stables, feel the greatest lassitude, even to weakness, whilst those of full blood seem invigorated by the same circumstance. When, however, the atmosphere of the stable be moist as well as hot, both breeds suffer equally in one way or another; laxity of fibre and profuse perspiration, with weakness, follow, and these producing an obnoxious effect upon the excremary organs, occasion in stables those stinking ammoniacal vapours that destroy the lungs, by disposing them to contract inflammation.

28. Besides the Glands just alluded to, that are situated in and about the solids and more secluded parts, and are so small and concealed as to be scarcely exposed to the sight or touch, unless when inflamed and enlarged by disease; other larger and more evident ones occupy the hinder part of the animal, of which we shall speak in their place. They are, 1st, the liver; 2d, the kidneys; and 3d, the testicles; the functions of each being tolerably well known. See sect. 52—55. and chap. iii. All glands, of whatever size or shape, are employed
in secretion, taking up and separating from other matters that quantity of watery particles which is constantly escaping out of one part of the system into another, by means of the cellular membrane, as described at sections 21 and 22. The smaller glands, just now described, have each a small tube attached to it, which seems intended to hold the acrid, or otherwise noxious, matter, which its lymphatic had refused to take up, as being at variance with its function; here it remains concealed, until the proper occasion arrives for carrying it off, and which may be found by one of the three natural evacuations; but these failing, it is clear disease of one sort or other must ensue. Perspiration seems to be its most natural mode of passing off; unless the demand for that kind of evacuation happens to be low, and then it is drawn to the kidneys (sect. 22). But, if the discharge by dung has been so copious as to afford too little of this acrid matter (essential probably in a certain degree), by means of the absorbents of the intestines, then, and in that case, it is taken up once more. When the animal's spirits are low, the absorption imperfect, and this offensive matter lies a long time in the tubes of these small glands, a general languishment of the beast takes place (called lentor by the old farriers); he perspires upon the least exertion, becomes unnerved, shows a rough hide, and refuses his meals. This constitutes "low fever," when the whole animal system is affected. This state of things, which is very common, points out the impropriety
of now resorting to diaphoretics (sweating powders); for it has been neglected so long, that tired nature, being offended thereat, refuses to part with those particles which occasion the greatest injury. "By the urine," be it said. This way offers the same difficulty, and the answer resolves itself into our plan of opening the principal evacuations first. See what we shall offer concerning bleeding and purging in a subsequent page. So much, however, seemed necessary to be advanced here, that the reader, who reads straight an end, should be at no loss as to what lately passed between us concerning secretion and effusion at sections 21 and 22. Of all the smaller glands, the best recognised are those termed salivary, situated near the jaws for the secretion of spittle, wherewith to moisten the food while descending into the stomach, and thus assisting digestion in its first stage. The strangles and vives are disorders of these glands: the swelling at this part is a corresponding symptom of glanders, and sometimes attends farcy. But the largest of these minor glands is situated in the solids, and lies within the buttock, concealed near its centre, into which passes an immense quantity of blood for its size; since it is found in the dead subject most disposed to putrify, especially when the animal has been driven hard; they then call this the kernel. The three large glands (p. 93), are reckoned so many organs of life, or vitals.

29. Lymphatics are one of two species of absorbing vessels; the other species (the lacteals)
being reserved for description under the head of "digestion," at sect. 44. Lymphatics are small tubes, with mouths that suck up or absorb the thin watery particles of the solids, one or more being placed on each gland of these parts. Some idea of the important nature of this part of the *animal system* may be formed from the circumstance that mercury applied to a part of the body particularly glandular, undergoes immediate absorption by the lymphatics, and is conveyed by this means through the jugular vein to the blood. Persons who may be unfortunately ordered to *rub in* mercurial ointment on the thighs will feel a fulness under the left ear in the course of a few minutes, according to the previous state of their bodies. How mercury acts upon the second species of absorbents—the lacteals, remains to be seen hereafter. The tendency of both is towards the heart, or rather the left collar-bone; increasing in size and diminishing in number, until the lymphatic duct meeting with the milky juices of its co-absorbent in the thorax, the mixture soon becomes blood by the action of air in the lungs, as described at sect. 39. As the lacteals, it will be seen, absorb only *nutritious* juices, so the lymphatics absorb none but *offensive* ones, as the matter of diseases, wounds, spavins, broken bones, ulcers, and the useless part of the deposite made by the arteries, as said at section 27; these being mixed, recompose *blood*, which passes through the heart, there receives fresh vital powers, as hereafter is described, and thence to the liver, there to be purged of its bitter quality,
which, passing incessantly into the intestines, is soon eliminated with the dung. At least, such is the natural course in health; a change takes place when these organs do not perform their functions aright, and we can perceive this misfortune in the dung, when the liver is at fault, particularly in the yellows. The importance of stimulating the lymphatics in all disorders of the outer surface, as mange, surfeit, farcy, &c. must be evident: as it is, also, in cases of tumors, as poll-evil, fistula, and quittor.

30. The nerves, like the glands, run in pairs, mostly, to all parts of the body; they are the organs of sense, communicate immediately with the brain, and are thus principally concerned in the function of voluntary motion. That the horse entertains likes and dislikes is certain; he has a memory too, both for persons and places, as every one knows; he must, therefore, have perception, and he is kind and docile in his nature, which entitles him to a kinder return from his master than he usually receives. We have often lamented that he was not endowed with one more faculty, even in the smallest degree, that he might distinguish between those who really love him, and those empirics who make a profit of his sufferings; he would then be induced, probably, to kick some among them, as examples to all the rest; and we never hear of one of those fellows, or their employers, being unhorsed, but we think of retributive justice. So, when the horse is girthed up unmercifully, in such a manner as to obstruct his respiration, he fre-
quently attempts to bite the operator. As the nerves of a horse are the seat of no distinct disease (the relaxation of the curtain of his eye being a constitutional defect), and all further explanation would be unnecessary, we shall content ourselves with adding, that they consist of small cords, white and roundish, like threads; and are certainly the vehicles of pain, which vibrates from one to the other, pleasurable sensations being conveyed by the same means to the sensorium, or brain*. The nerves are closely connected with the circulation, as well as with the brain, where they originate.

Reader,

31. Respiration is the act of drawing in the air by the expansion of the lungs, the cells whereof thereby become filled to their utmost, the ribs are distended, and the midriff pressed back upon the stomach, liver, &c. This is inspiration; the ex-

* Conscience (consciousness), which agitates the nerves by the faculty of thinking, when applied to the evils that are in the world, does sometimes cause the accession of fever to those delicate organs in human nature; but brute animals, being denied those powers (or of memory, except as regards the means of prolonging life) are little likely to contract "nervous fever;" although that state of fretfulness some high-bred horses are prone to, partakes of a good many symptoms of the human ailment, and may be cured by the same means. Sedatives, quiet, and a cooling regimen are those means. The loose stable now much adopted, contributes greatly to soothe the fretful horse. When the same fretfulness, or despondency, comes over a horse, out of condition, or whose condition has been recently reduced, he acquires low fever. See what is said under this head in Book II.
pulsion of the air, forming the re-action, being termed *expiration*; both together constitute what we call breathing or *respiration*, and the matter was before introduced (in section 26.) when we noticed that powerful auxiliary of this function—the midriff. Now, as we have always attached much importance to the act of respiration, seeing its close connexion with the formation of blood, and the almost constant state of disease in which are found the organs that contribute to this great function of animal life, we shall enter into more minute particulars respecting these, than we have thought necessary for any of the preceding organs. By this course, the reader will be enabled to form more distinct notions respecting the forming and "circulation of the blood," and its concomitant, the formation of *chyle*, commonly called "the Digestive powers"—both of them functions most essential to health; but, unhappily, both together become, by contravention of those powers, the fruitful source of numberless ills, we thence call constitutional or bodily disease, as fever, abscess, farcy, &c. To this point tends all that we have hitherto said concerning the inside of the horse; and the inquirer after veterinary knowledge will find his labour in studying this portion of it amply repaid, by the *just principles* upon which he will subsequently conduct his practice.

32. The *lungs*, or lights, are two well-known spongy bodies (*i.e.* *lobes*), having at their conjunction a small lobe nearer to where the *pipe*
enters that is to inflate them. At the same place is fastened the ends of a thin membrane, or rather two membranes, that enclose each one of the lobes; this membrane is termed the pleura, and seems designed to admit of one lobe performing its functions whenever the other may, at any time, be diseased. Between the two lobes the pleura is double, and, from its situation in the middle (in medio) is called mediastinum: it forms a passage for the great blood-vessels running near the spine, and is very liable to contract cold, which shows itself in "thick wind," or rather short wind. See sect. 36. In the pleura, then, are wrapped up, as in two silk handkerchiefs, the two lobes of the lungs, the upper part of that membrane being fastened to the spine and ribs; and on its surface is generated or secreted some of that oily fluid we before spoke of (sect. 20, 21), which is designed to keep the parts moist, and prevent their adhering together. His powers of secretion, however, and those of this organ in particular, often fail in the horse, in consequence of his very great exertions, combined with the heat of his blood, exhausting more than the secretory power can supply; and we frequently find the pleura growing to the ribs, the lungs, or the midriff, by reason of its wanting a due portion of this oily fluid; from the same cause (a defect in the secretion), we sometimes find the upper surface of the stomach partially attached to the midriff, evidently caused by inflammation of the parts. But whichever of those misfortunes attend the horse, he is invariably "hurt in
his wind,” suffers much pain at the commencement of a journey, and subsequently, if pushed hard, dies of locked jaw, through excessive suffering. Disorders of this nature were hitherto unknown to farriers of any description, being mistaken for the worms by every one who has written a book upon horse diseases; and, by the most eminent veterinary author of modern times, the last stages of this malformation are vaguely noticed by the erroneous terms of “debility” and “general debility,” which may mean, any thing amiss. Lentor, or slow fever, however, is the more immediate consequence, as mentioned higher up, in section 28.

33. The wind-pipe, as its name imports, is the pipe or tube for conveying to the lungs the air which every act of inspiration draws through it; extending from the mouth to the lungs or lights. At their conjunction, this tube divides into two branches, one penetrating to near the bottom of each lobe, and these again having a dozen perforations apiece in their sides, inflate an infinite number of little tubes, or cells, which compose the lungs, much in the fashion of sponge. Except eight blood-vessels, which enter the horse’s lungs, the intervals are filled with cellular membrane, and these being also connected with the same kind of membrane in all other parts of the body, accounts for a phenomenon we shall take occasion to notice shortly (sect. 34), in the case of a blown horse.

At its upper end, the wind-pipe is composed of strong cartilaginous plates, connected together by
ligaments, and put in motion by small muscles for producing the sounds expressed by the animal. Next to the entrance these cartilages, which are there strongest, form a curious kind of chamber, termed epiglottis, over which is a lid or valve (the glottis), placed there to defend the passage into the air-tube, from the entrance of victuals, drink, &c. For, upon the descent of any such substance, this valve shuts down like a trap-door, and they pass over it. No sooner, however, are they gone past, than up rises the valve again, lying back towards the mouth upon the palate; and being very large in the horse, accounts for the gulps with which he takes in water, and his peculiar mode of feeding. For the same reason it is, that the horse breathes only through his nostrils, between which and the wind-pipe there is a close affinity in some diseases (as the glanders) and accounts for his in-capacity for bellowing like the ox, or vomiting like man. At this spot it is, that certain savages in human shape press the finger and thumb with brutal force, in order, as 'tis called, "to cough him." No certainty, however, lies in this imagined test of his wind; for, although a thoroughly broken-winded horse will not cough, yet one which is partly affected will do so in most instances; whilst the soundest horses do most obstinately resist the coughing; and in a few, the circular cartilages so well defend the muscle, as to defy the prevalent inhuman effort, and seem to rebuke the ignorant attempt "to prove the goodness of his wind."
CHAP. II.] COUGHING: A COLD, ITS PROGRESS. 103

34. Farther towards its lower extremity, the wind-pipe becomes more membranous, but less sensible of injury, and the cartilaginous rings gradually lose their form: they no longer describe a circle, being composed almost wholly of strong elastic membrane, that it may bend out of the way when the gullet is distended with swallowing. Its internal surface is lined with a membrane, which incessantly secretes a quantity of the oily or mucous fluid spoken of in sections 20 and 21, thereby defending its coats from the action of the air in passing to and from the lungs. But this secretion being sometimes exhausted by the very great exertions of the animal, he then coughs so as to shake his entire frame, as if to incite the membrane to make fresh secretions of fluid for its defence; or, in default thereof, the cold air still rushing in at each inspiration, he contracts a permanent cold, or catarrh, which if suffered to continue, increases and runs along the membrane to the lower branches of the pipe, and ultimately communicates its baleful influence to one or both lobes of the lungs. If the attack be trivial, small green spots are found on the surface of the lungs, which would form ulcers, increasing in size and number, according to the number of small tubes or cells affected. These tubes lose their functions in consequence of the first attack, the animal's wind becomes worse every time he is hard pushed, and the cells burst into each other, until, perhaps, one lobe, or half of his lungs is rendered useless. In process of time, it turns as
black as one's hat, infects the other lobe, and mortification ensues, which is rather accelerated by the cordials with which the poor creature is usually punished, and it dies.

But when it so happens that too much of the oily fluid is secreted in the wind-pipe, as is the case with well-conditioned and otherwise healthy horses attacked with slight colds, the animal snorts or coughs it off by a sudden natural effort; wherein, the midriff being made to press forcibly upon the lungs, by the sudden contraction of the muscles of the lower ribs, out flies the wind through the nostrils, carrying with it whatever may have adhered by the way. This occurs often in training, when the horse has been put beyond his due lengths, at his utmost pace. Whenever this is the case, the membrane that lines the nose inside becomes irritated, and fresh accession of its own secretion, thickened a little, is the consequence; inflammation of the part, ulcers, and a running of foul matter ensue—and this, if the blood be not in a good state, soon becomes that obstinate malady—the glanders. Horses of good condition never contract the glanders, though they may catch the infection; in fact, good keep will generally cause glanders to run off.

An instructive experiment may be made upon the pluck of a sheep—the relative situation and functions of these parts in all quadrupeds being the same, except that the sheep's lights, compared to those of the horse, are not so long in proportion to their thickness. Take a pair of bellows, and hav-
ing introduced the nozzle tolerably well into the wind-pipe, tie it round with a cobbler's end; then, blowing hard with one hand, while the other is employed in squeezing the pipe, to prevent the escape of the air back into the bellows, you may form an accurate notion of the effect of inspiration. The lights or lungs at first give out the whole of the air which has been driven in, and may be inflated to an enormous size; but, if much force is used, the cells burst into each other, some appearing on the surface thin and transparent, and refuse to give back their wind; this forms "broken wind" of one description, and is that wherein the expirations are slower than the inspirations—the pleura being then affected in its thickest part, and the midriff also. Out of the first part of this experiment may, likewise, be derived a more accurate knowledge of what is termed "second wind," among sportsmen: when the animal (or man) has made great exertions, so as to fill all the cells of his lungs to their utmost, and then relaxes from the labour, he finds himself renovated, the cells being rendered more capable of distension and expulsion, when each inspiration and expiration also occupies more time and less labour.

Sporting men, who are fond of our bear-baitings, Pecora-fights, and monkey scratches, may daily witness a practical natural illustration of the same doctrine, in the conduct of the bear towards his antagonist. Seizing the dog between his paws, he squeezes him up till he gasps for breath, when
Bruin, being muzzled, rams his nose tight into the dog's mouth, and, blowing with all his might, you may hear the wind whizzing: the dog swells all over, by reason of the air entering the cellular membrane, and he dies unless timely pulled off. A dog which has "had a hurt" of this sort seldom regains his proper wind; he must be "a good one" to face the bear again, "as long as he crawls." Such is the polished language at those elegant places of town amusements.

35. The midriff has been already mentioned (sections 25 and 31). It is termed diaphragm by the learned; and we have seen how materially it is engaged in the business of respiration. But for the action of this drum-head-like membrane, neither the lungs on one side of it, nor the stomach, bowels, and liver, on the other, would obtain their full degree of motion, which is thus kept in tune, as it were, by those organs acting alternately upon each other: the action of the heart, too, is in unison with that motion; but when through agitation (occasioned by great exercise, fright, &c.) it does not keep time, the temporary disorder, termed palpitation, is the consequence. We may infer that, when the lungs have discharged their contents, the lower or thinnest end of that organ, falling upon the muscular border of the midriff, is by it repulsed and excited to action. Any man can feel, when he has expired all his wind, a kind of throbbing internally, lower down than the heart, until he inspires a fresh portion of air. When the lungs are in such
a state of supineness, those of the horse are about three or four inches thick at the conjunction with the wind-pipe, and ten or thirteen inches from thence to each extremity, according to the size of the subject; but, when fully inflated with air, they together fill up the whole cavity of the chest, obstructing in a trivial degree the vibration of the heart: then do they reach to the enormous difference of twelve or thirteen inches in thickness, and somewhat more than double in length. At least such were the dimensions of this organ in a horse which was opened by us in May, 1820: he was of the cart-horse breed, under sixteen hands, and healthy in other respects than having been blown by eating too much corn; whereby nature was compelled to leave the lungs quite full at the moment of his death. The same subject is alluded to in the 26th section, where we intended to illustrate the formation and functions of the cellular membrane.

“No part of the animal has been formed in vain,” as we before observed (section 23): quadrupeds and bipeds both press the earth which gave them birth, and which affords them the means of prolonging life; accordingly, this order of beings is furnished with a midriff; but fishes and insects, having no such occasion for this organ, are without it: neither have birds a midriff; but Mr. John Hunter was of opinion, that the want of it is supplied by the hollowness of the bones, which not only increases their buoyancy, but that the air con-
tained in them re-acts upon the lungs in the same manner as a midriff would do.

36. In health, as in disease, the midriff is liable to be affected by its neighbours, both before and behind it, the stomach often communicating its state of feeling to the lungs through the midriff; for it is by this medium that medicines impart their beneficial effects upon the lungs, as may be experienced upon our swallowing cold water at a time when our lungs are heated—the relative situation of those organs being much alike in man and in the horse. Immediately hereupon, a sensible difference takes place in the number of respirations; and the quality thereof is also changed from a hot to a cooler temperature: well be it, if the suddenness of the check do not occasion inflammation of the lungs: again, whoever swallows spirituous liquors feels an immediate disposition of the lungs to repel the heated air of the cells which lie contiguous to the midriff; the first breath which escapes the mouth being less heated than that which follows and finishes the expiration, and imparts a sensation wholly different from the vulgar belchings of an overcharged stomach. These come up by the way of the gullet, and carry forth a nauseous effluvia; whereas air from the lungs is ever sweet, unless this organ be already in an advanced state of decay. This state of the case leads us to make one practical observation, which shall not be set down, as more curious than useful: out of seventeen
subjects, which successively fell to our lot to examine as to the immediate cause of death, only two, tolerably sound at the lungs, presented themselves; which we take to be the fair proportion of sound horses, as respects the lungs, of all that live or die. All those cases occurred from February to May, a season when such an affection might not be considered most prevalent. Hence we conclude, from all that has been said, that a tolerable good guess at the state of a horse's lungs may be formed, by smelling at his breath after a canter, in like manner as our Smithfield dealers smell the animals' nostrils, in order to detect the glanders.

From what has been said, it follows, that a diseased stomach may be produced by diseased lungs, and vice versa, and that the midriff suffers in either case: then does the midriff become livid, purplish, and inflamed, with dark-coloured stripes, as if thickened at such places, the muscular border thereof assuming a putrid appearance, and sending forth a villainous stench. When this is the case, or any other ailment prevents the midriff from performing its proper function of inhaling and expelling the air from the lungs, that species of "broken wind" takes place which is known by the sort of breathing wherein the expirations are quicker than the inspirations; being thus contradistinguished from that other species of broken wind, which is occasioned by rupture of the air cells. A paralysis of the midriff, or the adhesion of the stomach to its lower side, is equally obstructive of its re-action
upon the lungs; and we have this day, (May, 1820), cut away an adhesion of this sort as wide as the palm of a man’s hand.

Unfortunately for the horse which is affected either in the midriff, the lungs, in the pleura, or covering thereof, his doctors heal the whole series in the same manner, not unfrequently including, in their uniformly mistaken practice, the affections of the stomach, liver, pancreas, and kidneys. In all, the inflammatory symptoms are predominant, and a cooling regimen presses itself upon our notice as more proper than the best of medicines, although having the same tendency; whereas, the direct contrary is the practice mostly followed, and heating medicines, under the fascinating name of cordials, made of spices, ale, wine, &c. are administered daily. Or, at most, if a sedative or opiate, by chance, finds its way (properly enough) into the animal’s stomach, this organ is thereby only rendered more susceptible of the heating mixtures which are again had recourse to immediately thereafter.

** Now, Reader, let us take a rapid glance behind us!

The organs of respiration are liable to seven or eight several kinds of diseases, mostly originating in the horse’s having caught cold; they are denominated according to the particular place where he may be affected, and in one respect, according to the degree of attack. A cold (simply) or catarrh continuing, produces that affection which denomi-
nates the patient "a roarer." Chronic cough brings on "broken wind," of which there are two sorts; and consumption usually follows the long continuance of either. So, when either has continued awhile, and reduced the animal's strength ever so little, he is said to be in a consumption; "worn out," is also a common phrase, as is "rotten;" "debilitated," and "done for," stand a little higher in gentility; but all mean, that there is small chance of his recovery.

Pulmonary consumption is the only kind which may justly be attributed to constitutional defect; i.e. heated blood, with viscosity, causing overmuch action of the parts (see section 32), when the pulse becomes powerful and quickened, and the horse seems anxious and fearful. Should it subside by judicious treatment, or the natural strength of the horse, he commonly retains so much of its effects as to cause great danger whenever he may catch cold, or be worked too hard. This attack is too frequently neglected, or put off with the remark, "only a little touched in the wind," unless by the addition of a cold, the disorder comes on rapidly, when it is termed "inflammation of the lungs," and the animal goes off in four or five days, if he be not promptly relieved. On dissection, the parts are found spotted with a livid colour, and evident gangrene: every variation, indeed, is equally appalling to humanity, and we have often wondered how the horse could have lived an hour under such horrid circumstances.
A cold, simply, or catarrh, commences by inflammation of the lining of the wind-pipe, which may be confined to some given part of it, or extend itself generally from the nostrils to the lungs, both inclusive, much resembling “a cold” in man; in either case, much matter is secreted, and thrown off by snorting: when the attack is confined to the upper part of the pipe, and lasts some time, the horse becomes a confirmed roarer, his groan bearing great resemblance to the roar of some wild animals, and he is equally incurable.

Chronic cough, is that obstinate cough which remains and plagues the horse long after vain attempts at curing his cold ought to have taught his tormentors the inutility of their endeavours, and the dishonesty of their prescriptions. Broken wind is of two sorts: the first is caused by the rupture of the air cells of the lungs by over exertion, in which the expirations being slower than the inspirations, he is, aptly enough, said to be “broken winded;” the second kind of broken wind is known by a breathing the direct contrary, and is occasioned by the cold having settled upon the perforations of the branches, and enlarged them, so that the air escapes too readily. Thick wind, on the other hand, arises from the secretion of the pipe getting into the cells of the lungs, and affecting the orifices or perforations by thickening them, so that the air passes through with difficulty. Similar symptoms attend inflammation of the pleura (section 15), particularly when it reaches to the mediastinum, or
double part: as they do when the muscular border of the midriff is affected. But all these, though rightly considered different diseases at the commencement, in the horse, very shortly become one common affection, more or less, of all the organs of respiration: inflammation predominates over the whole series; and if the performance of his duties does not render them fatal, an injudicious treatment will fix upon him an incurable disorder, until the knife terminates his usefulness.

Lafosse, junior, observes, that, "Flat-chested horses are almost always subject to consumption, whilst (again) consumption narrows the capacity of the chest, and reproduces itself—there is no remedy for mis-construction." He further says, "Short wind is either produced by disorders of the breast, or it is a fault of construction, and both are irremediable. Such a horse is generally of less use than one that is thick wined."

Adhesion of the lungs to the adjacent parts is of frequent recurrence, and happens often, if not always, upon inflammatory attacks, and on excessive quick and long work. It goes off with rest and the cooling regimen, after showing a staring coat about the chest, and is a disorder that belongs to the abdominal viscera also; but we know not to a certainty when it prevails while the animal lives, and, therefore, do not mean to treat it as a specific disease. The reader will find numerous particles of information on this very interesting topic referred to in the Index, under "Adhesion and Cohesion."
37. Reader, the circulation of the blood is carried on through all parts of the body, to which it affords the means of life and health; or, being ill performed, is the fruitful source of lingering, obstinate, and often incurable diseases, some whereof almost baffle our skill and care; and, while they induce us to admit that the practice of veterinary physic never will reach perfection, inspires the hope that, by patient investigation, we may at least find out the means of alleviating their evil tendency. These considerations should excite particular attention to the subject in hand, being that to which all other functions are but subservient or conducive; respiration and digestion being more closely connected with it than any other, and requiring a corresponding degree of attention. The heart, jointly with the lungs, occupies the cavity of the chest, rather inclining towards the left side, against which its point may be felt beating, whenever the animal is agitated by exercise, or internally affected by inflammatory complaints. Its figure is too well known to render description necessary: in size it approaches that of an ox, and, like it, is enclosed in a membraneous sac, but very thin, not unlike a tight purse. Another sac, called the heart-bag, less tight, surrounds the former, but is never so large, nor encumbered with fat like that of the bullock. On opening this sac there issues forth a fluid which turns to water, if it were not so already; in the ox it is confessedly water, and rather more in quantity than in the horse;—the reason for
which difference we will show presently. So great is the stimulus of this organ, that its contractile power often exists long after the animal is dead, and the arteries cease to flow: a phenomenon that occurs when the horse is killed in full health, by an accident, or otherwise, while in full possession of its functions. In animals of much mettle or courage the heart attains to a great size, that of the famous horse Eclipse weighing 18lbs. In some horses, the vessels that nourish this muscular organ lie exposed on the surface, with others they lie wholly concealed; a fact from which we have yet found no opportunity of making any sure deduction, but apprehend it may arise from the breed, and conclude it must have considerable effects on the individual's disposition.

As the heart is the principal organ employed in converting into blood what is drawn from the finer particles of food sent into the system for that purpose, as well as in renovating that which has been exhausted of its vital principle in the circulation, it may well be supposed full of small blood-vessels. Four large ones meet at its thick end, and suspend it, by being attached to the bones of the back and ribs: two of them, bringing the dark vitiated blood from the extremities of the fore-part and of the hind-part, are veins; the other two large vessels are arteries, which, receiving the blood from the heart, just now refined by the process of nature, convey it with rapid contractions to every part of the system, there to give fresh vigour, and to impart health to
the whole. These contractions constitute the *pulsation*, or pulse; a criterion of health as of disease which we investigate with primal anxiety, as from it may be deduced the best prognostic of the state of disease, especially of inflammatory ones, to which this noble animal is more than any other subject, from causes to be explained hereafter.

38. Two large *chambers* (let us call them) and two small ones, each of the latter appended to one of the former, mainly contribute to the process of circulation; these, by their co-action, aid the contractile power of the heart, compelling the contents of the larger chambers to issue with much force into the arteries. But, before the blood can be thus again fit for circulation, nature has provided the means of rendering it so, by the action and reaction of these four chambers (or cavities) in the heart, contributing to refine it for that purpose; one large chamber, with its small one, being placed on the *right side* of the heart, and the like pair on the *left side* thereof. The blood from the veins flowing into the small chamber on the right side, irritates its inner coats, and they each contract upon its contents with nearly as much strength and quickness as we can open and shut the hand;—but certainly not *so much open*, although there is *a flap* on the entrance of each small chamber, which they liken to "a dog's ear," and call by the Greek word *auricle*, that being *an ear*. At each of these closings or contractions, the blood is forced out of the small chamber into its large chamber on the same
(right) side, through a small door-way, or valve, which opens only inwards, the door being too large for the door-way. By the way, these valves are very numerous in the animal system, principally as regards the circulation of blood in the veins; and the reader will do well to recollect, when we speak of valves in future, the illustration just given by comparing the same to a door-way, which bears a near resemblance to the valve. In the performance of this office, the heart may be said to have three several motions belonging to it: 1st, a quick one, by the contractions of the smaller chambers upon their contents: 2d, the contractions of each large chamber upon its contents, being just half the number of throbs made by the first mentioned: and, 3d, the vibration or tremor of the whole heart, in consequence of those other motions.

Well, on the right side still, the large chamber being filled with venous blood through the valve, or door-way, from the small one, becomes in like manner irritated so as to contract upon its contents, and to drive it out somewhere or other. Back to the small chamber it cannot possibly go; the valve does not open that way, as we have just now said; and, therefore, it issues with much more force through another valve into a short artery, which soon opens into two, like the letter Y, the heart being supposed at the bottom of the letter. Up rushes the blood to the top of the two branches—where it meets with—What? What do you think it meets with, gentle Reader?
Here, however, let him stop a little, and consider awhile; for, upon his rightly understanding what now becomes of the blood (thick, dark, and un-serviceable as it is), and how, in a trice, it becomes healthy, of a bright scarlet colour, and invigorating, mainly depends his being able to comprehend, by-and-by, what we shall have to offer concerning the diseases to which a vitiated or corrupt state of the blood gives rise. He will not, otherwise, make out sufficiently clear in what manner the blood of an animal can contract and retain that morbid state which shall pre-dispose it towards acquiring a constitutional disease that, however differently named according to the parts whereon it may fix, has but this one common origin for the entire series. To this page, then, we shall frequently refer him, when speaking to these points more in detail, hereafter; and he had best way, also, keep the book open at this place, whenever he may be endeavouring to comprehend what the learned veterinarians of the present day are striving to say respecting "the circulation," as they quaintly term it. Another of them, speaking upon the topic just brought to a conclusion, says, "The heart is divided into two cavities, termed ventricles, each having an auricle, resembling a dog's ear. The blood-vessels proceed from these [those] cavities, the arteries from the ventricles, the veins from the auricles," &c. All which is very true, but not very intelligible to the generality of readers; and yet is the author, who thus speaks, (Mr. White, in vol. i. p. 63.) fully
acknowledged to be the plainest spoken among the moderns; indeed, were he any thing else than a good common-sense writer, we should not have deemed him worthy of this remark.

39. *The Blood*, as before said, rushes out of the large chamber on the right side of the heart into an artery that soon divides into two branches; whereof one enters each lobe of the lungs, and there disperses, through certain cells, the blood with which it is constantly supplied. Here lies the secret! At this point it is, that health or disease (at least a pre-disposition to one or the other) is imbibed and engendered in the blood. The lungs having received the thick discoloured blood from the right side of the heart, and being the receptacles of the air we all breathe, do, by means of that air, bestow upon the blood afresh the principles of life, and health, and vigour. The cells, or tubes, through which the blood passes in the lungs, termed pulmonary, are eight in number, being double the quantity given to man, and show, from that circumstance, the immense circulation of which they are the agents. A cruel and almost incurable malady, that attends most horses at this part of the organs of respiration, with many and variable symptoms, was alluded to higher up, at sect. 36; and is what we term from those vessels, *pulmonary consumption.* But then, it is clear, that the *air* which is so brought to effect those beneficial changes upon the blood in the lungs, must be *fit for the purpose*;—that is to say, it should be vital or atmospheric air, uncon-
EFFECTS OF AIR ON THE BLOOD. [BOOK I.

taminated by any noxious stench (as the ammoniacal smell of the stable, or the stench and smoke of cities); no poisonous vapours (as burning brimstone, the gaseous fluid, smelting of minerals *), nor infectious effluvia (as of cesspools or stagnant waters, producing fevers, glanders, &c.) can give to the animal's blood that healthy vigour which was designed for his well-being; but, on the contrary, every departure from purity in the air he breathes must be an approach towards disease †. Yet, how constantly is this simplest law of nature transgressed! And what, in such a state of things, can be expected, but that the blood will assimilate in

* Scarcely any truth is easier proved than this: horses that are constantly kept in close stables, in large numbers together, very soon become unserviceable, by the constitution throwing off some evil or other upon the surface; as one proof whereof, those which are occasionally placed in the under-ground stables, at the Swan with Two Necks, Lad-lane, show evident signs of distress, which subside upon being brought into the air. We hear from good authority, that at New Orleans, in Southern America, where the atmosphere "exhibits a blue misty appearance," nothing is more common than a disease which affects the knee, hock, or pastern joint, with tumour, or near those parts with a species of cancer, and the limb actually rots off. The like kind of attacks were found formerly most common in Cornwall and in Wales, and are attributed by all to the arsenical vapours of the copper-mines being inhaled; they are, however, much less frequent at the present day, owing to the higher state of cultivation to which the land has been brought, and to the change of situation horses now enjoy. The free use of sweet oil is a good preventive of this poison in human as well as in cattle medicine.

† This is not the place for a finished dissertation on the communication of the glanders; but we must observe, in illustration of the text, that horses which have eaten glandorous matter without receiving the infection, no sooner smell it than they become diseased.
character with the kind of air the creature is compelled to inhale *? Accordingly, we find in the domesticated horse, that previous disposition to certain diseases which we endeavour to meet by correctives and repellants, but which by better treatment might have been prevented. Of these evils, abscess, or ulcer, is the most prolific, showing itself now on the head, at others on the feet, under the varied denominations of poll-evil, quittor, fistula, &c.; but more frequently attacking, and making the greatest ravages on, the internal organs, where it is generally mistaken for the worms, and is erroneously treated with hot and burning remedies, when evidently a direct contrary practice would best assist nature in casting off the evil †. Adhesion of the lungs, as it produces a staring coat, is too frequently mistaken for worms, and if the animal be not physicked and cordialled too much, a partial cure sometimes takes places, though in what way it

* In cases of much sorrow or grief, respiration is greatly increased; and the presentiment of death awaiting them, occasions all animals to take harmful substances into the lungs. Pigs, oxen, and even sheep, show signs of uneasiness, horror, or madness, at the effluvia of blood of their own kind; and we have found, upon slitting the trachea as far as the bronches, dust, dirt, or other rubbish, which they had snorted up in the last paroxysms of despair.

† Four ounces of spirits of turpentine have been given with partial success; but such a dose must go near to destroy not only worms but the horse into the bargain, whilst it is not very clearly proved that the small worms we sometimes meet with are hurtful to the animal, but are designed to act as a stimulus to the intestines; and, if the doctor mistakes for worms some more serious disorder, the horse dies of this monstrous medicine, as sure as fate. Consult Index for Adhesion.
is carried off is most inscrutable; but, upon opening the dead subject, we have often noticed spots which had been corroded and gangrenous, where the cure had been effected in this spontaneous manner. As for ulcers upon the liver, also arising from the viscidity of the blood, if they take place near its thin extremity, the common natural process is, that that part of the liver attaches itself to the gut, and the offensive matter will then slough off into the intestines, and come away by stool: a partial cure is the consequence; not produced by medicine acting upon the part, as is very clear, but by a common natural effort, aided by a more vigorous and healthy state of the blood than when the disease was engendered. To assist the circulation in regaining this state is clearly the duty of the medical attendant, and is the only manner in which he can be of any service to the animal in restoring it to health.

40. In the lungs, then, does the blood receive from the air its invigorating principle, and no sooner does this take place, than it drops into another short blood-vessel (a vein), and, by it, is conveyed again to the heart: not to the same small chamber on the right side, of course, but to a similar one on the left side. Here the contractions go on as before mentioned, only that the blood differs in quality; this being now properly fitted to promote the purposes of life, and for imparting the vital principle, occasions the heart to assume that twisted shape we see in some animals, while in
others whose bodily exertions and arterial functions are less laboured than those of the horse (the sheep's, for example) it is more round: and, indeed, the heart of this last-mentioned animal is, from this circumstance, usually termed, in the London district, a "round heart." Out of the small chamber on the left side is the blood driven through a valve, as before, into the larger chamber of the same side, which in its turn contracts, with much force, upon its contents, expelling the same into the great artery. This periodical rushing of the blood into the arteries, imparts to these vessels a motion we term pulsation, whereby the blood is propelled forward, to the remotest parts of the body. Lessening in size, and increasing in number, the branch-arteries which receive this blood, become more sensitive as they are farther removed from the heart, and afford us, at certain places, the means of ascertaining by the touch the degree of heat at which may at any time be the state of the animal's blood; the contractions of the heart being regulated, in quickness and force, by the degree of stimulation, the heat of the blood may occasion it. This is termed the irritability of the heart, and the medical test of which we speak, is called "feeling his pulse." Even in the tail may this contractile power of the arteries, and its effects be seen to advantage: when a colt is being docked, the blood squirts forth with frequent gushes, answering in a tolerably accurate manner to the state of his pulse, although the artery at that remote part is very small. But the blood that is so
changed in the lungs, as we have just said, is still found to contain certain particles or properties, which would render it unfit for the purposes to which it is to be applied, or those particles are required to effect certain purposes elsewhere in the system. Accordingly, the major part passes into the liver, there to be refined of its bitterness; whilst a portion is attracted to the kidneys, where it leaves its saline qualities, that pass off by staling, as the former is voided by dunging. See "Liver," at page 146; and Secretions, in the Index.

41. These purposes, however, are not always effected alike regularly, from several causes. Frequently, the blood comes to those organs in a state too vitiated for their utmost activity to cleanse; sometimes a diseased state of the blood, at others, languor of the parts, indispose them to the performance of their functions, and the blood is suffered to circulate, filled with humours that war with the constitution, and form what is termed "constitutional disease," or predispose him to receive disorders of varied malignity, according to circumstances. We shall come to advert to this point when, shortly, the liver and kidneys claim our attention; but, the chiefest cause of disorders incident to the animal by reason of defective liver, is the great exertions he is put to, and the consequent rapidity of the circulation, whereby the blood is propelled through it with tremendous velocity: it then acquires inflammation, and becomes ulcerated (see section 39.); a disposition which must be in-
creased whenever the blood has been formed imperfectly, either as regards the lungs or the lacteals. So much is this the case, that the blood drawn from a very aged patient of ours lately, that was incapable of grinding his corn properly, showed evident proofs that particles of ill-digested food had entered into the circulation, and is an answer to those writers who aver that the lacteals reject the bile and suck up only the fine parts of the chyle; whereas, all inquiring persons must know, that they take up the lighter parts of all substances whatever that pass through the intestines. If this were not so, how is it that the slow poisons just spoken of enter the blood? or how would it come to pass that so much good is performed by alterative medicines, that, in like manner, insensibly introduce themselves to the blood, and produce invisibly those permanently good effects we so much admire? The opposition of a few is no obstacle to this commendation of an obscure but safe and certain class of medicines,—to say nothing of an alterative regimen, which is more safe still, and certainly more natural, though slower and less positive in its effects than active medicine.

42. Blood-vessels, or tubes, we have already observed, pervade every part of the body, and are of two kinds, whose office is directly the reverse of each other. Arteries, it will be recollected, convey the vital fluid to all parts of the body, and the construction of these, it may easily be conceived, from what has been said, is simply that of a tube with
great contractile powers: they are large near the heart, but soon branch out of a lesser size, until, entering the smaller organization of the solids, they become very minute, infinitely numerous and more sensitive, thus affording the means of renovation, or growing, to the flesh, bones, skin, hair, hoofs, &c. The large artery communicates with minor branches, soon after leaving the heart, by two rows of openings, like perforations, in its lower side, at two or three inches asunder. Some one has likened the arrangement of these vessels to the stem, branches, and twigs of a currant-bush, and so might the veins that run nearly parallel to the arteries, through every part of the animal, but are so constructed and arranged, as to take up and reconvey the blood (which the arteries constantly deposit) back again to the heart; and the similarity will still further hold good, if we extend it to the leaves of the bush, and compare these to the glands (see sections 27, 28.), in every one of which an artery terminates, and deposits its nutritious contents, and where every small vein begins the absorption of what the artery had so left behind. This absorption, when obstructed, lax, or otherwise imperfect on the surface, may be restored by stimulating the parts with spirits; when it is too high, and labouring greatly in consequence of the viscidty of the blood, local inflammation is engendered, and one or other of those diseases we shall hereafter treat under "abscess," is the consequence of this constitutional derangement. Blood that is thick, heavy,
or viscid—call it which we like—causes heat, which being general, is *fever*; the rapidity of the circulation increases violently, and the blood now becomes more fluid than when the animal was in good health. Arteries may be distinguished from veins in the dead subject, by the property they possess, of retaining their tubular shape after the blood is discharged; whereas, the veins collapse, when empty.

43. If the arteries are plain tubes, lying for the most part concealed, *the veins*, on the contrary, are more frequently found exposed to the sight under the skin, next to the muscle. But, more delicate and more numerous, the veins perform their part of the circulation by a totally different means than is found in the propulsion and contraction of the arteries. One of the means of effecting this purpose is by the obvious and simple movement of the body and limbs, as well as by the act of breathing, whereby the blood is pressed out of some one part or other of the veins into the adjacent part; but these vessels being furnished with innumerable *valves*, within an inch, or less, of each other, the *doors* whereof open *only towards the heart*, the blood must necessarily force itself out that way, and no other. If we suppose that any given portion of the vein is hereby emptied, what follows from the circumstance, but that the *next-door valve*, which kept back the blood contained in the adjoining portion below, while it was pressed upon from above, being thus relieved from the pressure, will now open? Then, in rushes the blood, and the
space is again filled, but only to be emptied in a similar manner. It is with a view to accelerate the circulation through the veins, and to keep the blood warm in winter, that mankind betake themselves to forced exercises, as hunting, running, or beating the arms athwart the chest, and that beasts with the same propensity gambol and frisk about, or rub themselves: both promote the same ends, by breathing short, so as not to cool the lungs too much, or by drawing in the same warm air over again, in sheltered situations.

44. By the process just described, the blood being once admitted into the minuter veins, finds its way to the larger ones, which convey it to the heart; near to which, as the quantity becomes great in the large vein, it receives a powerful auxiliary in the filling and emptying of the lungs, and the working forward and backward of the midriff, as described before. Passing through it near the back bone, and, consequently, at its more muscular part, the great vein must, at every inspiration, receive from the midriff considerable aid in pouring forth its contents—to say nothing additional of the pump-like action of the heart itself. At this part the vein acquires the appearance of a double tube, the outside thickened and muscular, the inner one membranous and collapsed, as if too big for the space in which it is placed. But the curious fact—how the blood which had been sent into circulation through the arteries, gets into the veins at first, deserves consideration; as this must be effected
laboriously, when the *fluidity of the blood* is lessened, or else accelerated with frightful rapidity, whenever it so happens that *fever* prevails: *local inflammation*, by the same rule, must cause an unusual flow of blood to *the part affected*; and, as most of the impurities of the system will then be drawn towards it, at that place must they leave the occasion of the most direful effects. In proof of this doctrine, it happens frequently, that when an animal is attacked with inflammatory tumours at two places at once, the greater evil of the two *increases*, whilst the lesser one "*runs off,*" as it is called, or gets cured of itself. So, on the contrary, when a diseased horse (*glanderous, for example*) is well fed and well kept, he not unfrequently overcomes his disorder *without medicine,* to the great wonder of the unknowing; the solution whereof is, that the constant supply of new blood has quite changed the nature of the animal, his disease has been "*taken up,*" or absorbed, by the animal system, and ultimately carried off in the common evacuations. In short, *absorption* and *effusion* are the great internal secrets of animal life; although we cannot say with certainty how they are carried on, it is no less a positive law of nature, that the veins at their commencement in the glands *absorb,* or suck up, the blood that is deposited there by the arteries, and separated by the lymphatics; equally well known is it, that *effusion* takes place, of arterial blood, into much larger veins, as well as from one part of the system into another, internally.
These points are deducible from a multitude of facts and well-known operations, some proofs of which the reader will find more in detail in the course of this volume. In some parts, a positive connexion of the capillaries, or smallest blood-vessels, is found to exist; in such a manner, that the section of one or more of these, and the consequent obstruction of the means of life to all the parts below it, which some would naturally expect, is hereby remedied.

45. Reader, the process of digestion, whereby the food is prepared to be converted into blood, is no less curious than "the circulation" itself, is equally conducive to the support of life, and, being obstructed, is also the harbinger of disease. If, on the two other great functions of animal life, depend his immediate existence, no less does the horse's capabilities, his present health, and the engendering of future obstinate, incurable, and often mortal diseases reach his vitals by way of his stomach and intestines, which comprise the organs of digestion.

Every one knows that oats and hay are the chief sustenance of the horse in a domesticated state, and these, together with one or two other similar productions, and water, are given to him for nutriment alone; it therefore follows, that whatever substances are taken into his stomach, which act not to the same end, must operate injuriously, even though containing nothing hurtful in themselves: these must obstruct, if they do no
more. But, when matters obnoxious in their nature, and possessing strong powers and effects, are being administered to the horse, it seems but fair to examine whether such things are likely to agree with his common nutriment, with the blood that is made from it, or with his constitution, his habits, or the tasks he has to perform. Or whether, on the other hand, they do not prove destructive of the food itself, of the vessels that contain it, and of those which draw up its finer particles, that are to be converted into blood.

Let him who practises by violent means consider a moment the natural structure, formation, and functions of the organs on which his medicines are destined to act, and compare their altered state, that has been brought about by reason of the treatment the animal has received at his hands. Some protection, doubtless, is afforded by nature, (as if prescient of the race of farriers), in the secretion of the fluid so often mentioned, which defends the several organs against ordinary injuries; but these are often found insufficient in quantity (notwithstanding the supply which may be drawn by effusion from other parts of the body), and the frequent repetition of the monstrous mixtures of the doctor's skill-less art, ultimately effects its purpose in destroying the tone of the fine vessels just alluded to (the lacteals), and then the symptomatic disease of the skin, called hidebound, follows, as a natural consequence.

46. The stomach is a bag, or pouch, with two
openings in it; the one receiving the end of the gullet, the other opening into the small gut. See it in frontispiece [H—L, 26—29.] It lies behind the midriff, inclining a little to the left, having the lungs contiguous on the other side that membrane, and the liver next behind or under it. This main organ of digestion is but small in the horse, as compared to that of any other animal, being so designed to assist his fleetness, but which would be impeded by his receiving large quantities of food at a time, and points out the reason why he requires to be fed and watered frequently: the larger and more distended the stomach of any animal may be, the more sluggish and vicious he is. As one proof of this position, we formerly obtained the stomach of a man which was larger than that of any other subject we ever saw or read of, and its possessor in life had a heavy, slow, and sordid manner, together with one or two other bad qualities which brought him prematurely to his end.

At the upper orifice of the stomach, a membrane, nearly insensible, coming from the gullet, enters it loosely, and spreading along its lower part, lines about one half of it, thus defending it from acrimonious or poisonous substances, as well as from the farrier's "monstrous mixtures" before noticed; whilst the coat of the other parts thereof consists of striated muscular fibres, very sensible, and given to contraction, and running transversely to those of the insensible coat, a circumstance which has given rise to the fanciful notion, that digestion proceeds in
the horse's stomach by what is termed "trituration," or pounding; but, upon reference to the figure which illustrates another organ, (at page 158.) the reader will be able to form a more accurate notion, near enough for his purpose, how the stomach contracts its sensible part upon its contents. This sensible coat secretes a juice which, from its strong gastric nature, not only digests the food, but would also corrode the stomach itself (insensible though it be), were it not supplied with another fluid for its protection, in the saliva or spittle that descends the gullet along with the food. This saliva is also secreted, in some measure, when the animal may not be feeding: but, whenever this supply fails, the gastric juice predominates so much, as to cause a galling pain in the stomach, and occasion in the animal a ravenous desire for filling it, if not with food, at least with some substance that may keep it distended, and perhaps carry off the painful superabundance. Horses so circumstanced, when in harness, gnaw the pole or shaft, or bite at each other, and soon learn to become crib-biters, gnawing anything they can come near, as well as the manger; litter, bits of old wall, and dirt, at length, are found by them agreeable to their palate. See further at section 49.

The insensible membrane we spoke of, by its loose folds, forms, at the entrance of the stomach, a kind of valve, which prevents regurgitation of the food, like that of ruminating animals; and a similar contrivance at its termination in the lower or
right orifice occasions a short obstruction until the pulp is mixed; for, when the stomach is filled, the relative position of the two orifices alters in a good degree. From these premises it seems apparent that any substance entering an empty stomach does not act upon the sensible part of it, but being soon mixed up with the gastric juice, it proceeds into the intestines, there to communicate its effects—whatever these may be. Whether nutritive or medicinal, poisonous or beneficial, the intestines receive all with but little alteration*. But when it so happens that the food does not pass readily out of the stomach, a fermentation commences, and the sensible part thereof being then distended, the ill effects ascend the gullet, reach the head, and cause vertigo, staggers, &c. At times, a specific

* At this place, for the information of those who would practise the veterinary art by comparison, it may be useful to observe, that in the human stomach is digestion principally performed, in the horse’s very little; in both, the small intestines appear to mix the food with the bile and other digestive juices; but man having no cæcum, or blind gut, like the horse, to receive water and the heavier parts of the food as they escape from the small intestines, his lacteals begin higher up than those of the horse, which lie wholly on the large intestines. It follows that, whatever is received into the stomach of man is felt through the system immediately; with the horse this does not take place until it has reached the intestines. One other dissimilarity in the mode of digestion is worthy notice: in man, the work of digestion is nearly finished when the bile is mixed with the food—say at an average of twelve hours from its being taken, whilst the horse passes his feeds into the intestines in about two hours, before it has well assumed an homogeneous appearance, which the bile seems mainly to effect for him. With us liquid remains in the stomach; the horse passes water immediately into the cæcum.
inflammation takes place, and communicates itself in four or five days to the whole of that surface, taking its course downwards or upwards, according to the orifice that may be most affected; the first communicating all the way down through the intestines, blocking up the influx of gall (as described at section 48.), and causing yellowness of the eyes, until its appearance at the anus; or, in the other case, it ascends up to the nostrils, making its appearance first about the head, and communicates either way to the skin and its coat.

47. Of the intestines, it is important to keep in mind, that, notwithstanding the appearance of great tenacity they assume, they are, nevertheless, extremely irritable, being composed of two coats of fine muscular fibres that cross each other, the one circularly, the other lengthwise; and having a lining which secretes a fluid for its protection, they admit in their intervals an innumerable quantity of absorbent vessels, that are constantly sucking up the finer particles of their contents. This sort of conformation renders the intestinal canal obnoxious to repeated strong drastic purges, particularly those which receive the name of horse aloe, that heat and irritate the parts by their coarseness. Inflammation is most likely to succeed such irritation, in summertime especially, and the animal is usually destroyed by the pretended remedies of the farriers; or, being pressed forward in his work during the attack, goes until he drops down and dies. At the fundament may be seen the earliest indication of this species of
overphysicking, in the disgusting protrusion of the inner coat whilst expelling the contents thereof; an ordinary effort of nature to get rid of what is offensive to it, which, considering the horizontal position of the horse, might appear wonderful to us bipeds but for the well-known double operation of the coats of the intestines. From the top to the bottom of the canal a spiral motion is kept up by the alternate contraction of the two coats thereof, the one in circumference, the other lengthwise, resembling that of a worm, and appearing as if a cork-screw agitated its inside. By this means the mass is pressed backwards, and as it increases in quantity and becomes less and less clearable, the offended nerves excite the guts to renewed efforts for its expulsion, in which the lower part of the belly, with its covering, from the cæcum to the sphincter, concur with all their powers of contraction. Partial retention of the breath, and consequent pressure upon the midriff, and parts behind it, contribute to lessen the longitude of the intestine at every effort. This kind of excitement, if repeated too often, it is plainly to be seen, must keep up the irritation of the parts concerned in it inordinately, and dispose them to contract inflammation.

48. In length about thirty yards, the intestinal canal has in its course two or three different offices to perform towards digestion, whereof the smallest gut nearest the stomach is for receiving the gall, or bile that has been formed in the liver for that purpose. At the termination of the next small gut,
at the end of twenty yards, an immensely wide one occurs, called the sac (caecum), or blind gut, whither the contents are prevented from passing in too soon, by reason of the internal coat of the small gut getting into folds, as 'twere. We may as well consider this as another valve; and that it was provided by the Author of Nature to correct the animal's propensity for transgressing his laws against repletion, as well as to prevent the contents of the caecum from returning upwards, when this latter is compressing the large intestines backwards, in the act of dunging. But inflammation sometimes, obstructions oftener, produce at this place more tedious affections than is generally imagined. When it so happens that the stimulus of the bile is insufficient (as in diseased liver), and acrimonious particles are left behind, or the half-masticated food inflicts injuries on the very sensible surface of this passage, then the noisome effluvia re-ascent to the stomach; the bile, too, enters it soon after, by reason of the intestines having lost their power of compression and elongation, when the cork-screw motion downwards is changed to an upwards motion, and all becomes disorder in that region. Loss of appetite, fever and dullness, with drooping as if in pain, and a staring coat, follow each other in succession; for the secretion of bile, which I shall come presently to describe, as affecting the skin, is thereby vitiated. These appearances it has been a fashion to consider "symptoms of the worms," or of "debility" (another term
for low fever); and the practice of administering bitter medicines, that are supposed to kill the worms, is only successful on account of their restoring the tone of the stomach, and by supplying to the intestines a congenial stimulus in the place of bile. This was the case with Mr. White's statement, in vol. i. p. 170, where he says, "I have sometimes succeeded in destroying worms by giving aloes, one dram and a half, every morning until purging was produced." That is to say, "the horse became well;" but whether he had any worms to be destroyed is another question; and then, if a dram any a half would succeed sometimes, I should apprehend a large dose (as eight drams, his favourite quantity) would more inevitably have poisoned all the worms his horses may have had, of whichever kind they might be; but this latter mode, as will be perceived, though more destructive of any thing, would not have acted as a tonic restorative on the stomach and intestines, like small repeated doses. We, however, who are men of no fashion, generally have found those kind of attacks accompany a repetition of irregular feeding; that is to say, very little one day, very much another; now all, now none; the attack varying in degree, and changing from simple obstruction to the inflammatory, as the animal may or may not have been allowed sufficient water with his food.

49. To supply this deficiency, in some measure, does the caecum, or blind gut, seem to have been placed at the termination of the small intestines.
For, in this second cavity digestion is supposed to be completed, much liquid being found therein; and we know that here, in a corner, termed its "appendix," are frequently deposited hard matters, as earth, stones, and other substances, little compatible with the purposes of nutrition, as noticed at section 46; but whether these ever pass off by stool remains in doubt, and we are left to conclude that it is much less sensible than the other intestines. In size, it may approach to twice that of the stomach of the individual; and it is placed near the surface of the belly, lying on the left, about midway between the fore and hind near leg. Here it is exposed to damagement from a variety of causes; the stable-boy, while dressing him, often hits the horse here with the curry-comb; the dealer tries whether his new purchase is a roarer by striking him hard with his lash whip, whilst he holds up his head short; and we have frequently seen one of the most noted jobbers and breakers in London terrify his "restive customers" into obedience, by a kick of his foot skilfully placed on this part. The facts are quite notorious; what is worse, they long remained uncorrected. The consequence of this kind of hard usage is, that the cæcum * loses its functions, more or less, whereby certain heavy substances are not

* The muscles of the cæcum being stronger than any other part of the intestines, are compelled by the blow to contract forcibly, as do the intercostal muscles of the ribs, whereby the air in the lungs is suddenly expelled, and, if he be affected, the horse groans as the air passes the upper part of the wind-pipe.
expelled as they ought, but remaining behind, attach to their surface some earthy particles of the food, which would otherwise pass into the colon, and the heat of the animal's body causes these concretions to become stones of great magnitude. Six or eight pounds in weight, and nearly as many inches in diameter, are quoted as by no means uncommon sizes, in certain parts of the country where humanity is at a low ebb, and the police unmindful of their duty in this respect.

50. The colon, or large gut, commences at the only orifice of the last-mentioned sac; then, turning underneath the small intestines, and proceeding forward under the stomach and liver, it turns about, and, in its course backward, makes a great number of zig-zag turnings, by means of a membranous ligature that runs along its whole length, and coils it up. Such a shape, or rather no-shape disposition of its folds, would inevitably obstruct the progress of its contents, but for the fore-mentioned double motion of its fibrous coats, with which the colon is furnished, as well as the smaller intestines. Being heavy, it is suspended the whole length of the horse's hinder part, by a strong half-transparent membrane (called peritonæum), which being fastened to the bones of the loins, and hanging down in folds, or plaits, admits of the guts' filling up the same from side to side, in the semi-globular manner we may perceive when the animal is first opened. But, where the mesentery embraces the intestines the tightest, as if to prevent the too
ready escape of the food, there is placed along the whole length of the depression, between the folds of the gut, a white vessel having numerous branches full of nutritious juice, making its way towards the fore-part of the animal. See the figure at page 14.

This is the lacteal duct, which, from its situation between the folds, formed by the mesentery, is by some termed "the mesenteric canal," and by and by (in Gibson) "the mesenteric artery." 

Merscolon and mersrectum being the names of parts which usually merge in the general term "mesentery" for the whole, we have made no distinction. But all this does not signify so much as the manner in which this duct gets filled at first by the lacteals, how it constantly flows in health, or is obstructed in disease, and what is the mode and the effect of discharging its contents near the heart, as before alluded to in section 37, second paragraph, as well as just below, in section 51. Herein may be found much matter for pleasing reflection and study, by him who aspires after obtaining a more accurate knowledge of the curative art than is generally possessed; and to attain to perfection wherein, he must study the thing itself by inspection, since nothing we can find room to set down here can give him any thing like an adequate notion of its importance; nor, indeed, was it ever our intention to employ strict anatomical description, or to enter into learned definitions, any farther than should be found necessary to illustrate what we have to teach, respecting diseases in general, and some long-standing
errors of respectable veterinary surgeons in particular. On no other point, throughout these labours, do we so much desire to be rightly understood, as on this one of the absorbents, and absorption altogether*; for it is only when this function takes place with regularity that health can be preserved: when it is disordered, our business is to restore it, too much or too little being equally productive of a disposition to diseases, though opposite ones. An indolent or an impoverished absorption requires our care no less than a too rapid or feverish performance of this function: the flaim and cathartic medicines reduce the latter kind of symptoms; a generous mash, tonic alteratives, and good grooming, are the best restoratives of a languid system. Pulsation is the test of either state of derangement; and he who is the cleverest at discovering, by this prognostic, what is going on in the system, will always make the most humane, as well as the most successful, horse-doctor.

51. Towards its termination, the colon makes a short turn, as if to prevent the too easy escape of the dung into the rectum, or arse-gut, without an effort of nature to straighten the curve at that place; as we see it performed when the animal strains the part, while contracting the lower muscles

* Generally termed "the absorbent system," and, until lately, wholly unattended to in veterinary practice; Gibson, in his lengthy particularities respecting the horse, not having once mentioned the lacteals (as if they existed not), and contenting himself with just loosely naming "lymphatics," at page 55 of his first volume.
of the belly, together with the cæcum, in order to produce a stool—the whole transaction being most intelligibly termed "a motion." Several such impediments occur in the course of the intestinal canal, and some of them are so abrupt, as no after-art is ever capable of reducing to a straight line; the reason for which kind of contrivance is, that its contents still possess some nourishment, which it is desirable should be extracted, and they are thus detained that nothing might be lost; to say nothing of the existing opinion, that the food which has thus lain some time in the animal must impart a juice differing considerably in its properties from that which was but recently received into the stomach. No operation in the system is more beautiful than this one of drawing from the food, now properly mixed and softened, what becomes the milky fluid, called chyle, first, and blood immediately afterwards; the first mentioned being performed by innumerable transparent vessels, whose fine mouths open every where on the inner surface of the intestines. From the word laeta (milk), these vessels are termed lacteals, their function being absorption (like the lymphatics); the largest whereof lying along the mesentery (as I said before), sends out smaller branches, and these again more minute ones, to encircle and penetrate the gut; in this their mouths do incessantly suck up, or absorb, and convey to the larger vessels the material for replenishing the system with new blood. Passing along the spine, the large tube, filled with this milky fluid, at
length reaches the fore part of the animal, and acquires the name of the *thoracic duct*; here it mixes with a portion of *lymph*, and is conveyed immediately by a large vein to the heart. Ascending the pulmonary artery, as described in a former section (37), the air entering the lungs, changes its colour to a fine healthy scarlet, and at the next pulsation it is driven into the circulation, to mingle with the mass, to impart its newly-acquired properties, and to return again and again, wasting away, until at length it becomes used up and extinct, its place being supplied with other new materials for making blood by the continued process of digestion. This *wasting away*, in what may be termed the *wear and tear* of the animal system, is constantly going on, whilst the new constantly supplies the place of the old blood; thus effecting a change of substance, which is said to take place with the whole body of the horse in the course of every year and a half, or two years; so that at no time has he a particle of flesh, bone, hair, hoof, or other matter which formed his body two years before, and affording a fit subject for reflection and admiration in us, as it invites those who have the care of providing for his health to take advantage of the well-known circumstances, the more securely to effect those changes by *gradual means*, which too frequently are attempted by violence, and fail. Nature will not be forced; rather seek her in her recesses, and humour her ways. Those who act differently, generally induce some lasting disorder to
appear upon the surface, which they treat as if local; when, alas! these are seated in the very vitals of the animal, sometimes in the most delicate parts of the mesentery itself. Heating, or cordial medicines, as well as those other untoward mixtures, which corrode, or blunt, the mouths of the finer lacteals, thereby dispose them to receive materials improper for the making of good blood; the consequence whereof is, that tubercles frequently are found, which fill up the cavities of the lacteal duct. The matter of these tubercles is usually indurated, and resembles the yolk of a hard-boiled egg. The disease appears in a staring coat, is commonly considered to be the worms, and treated as such, with more heating or drastic medicines, which but increase the evil. Other obstructions are thereby formed, and if a solitary worm or two should be found on dissection (as frequently happens), they have been generated in the obstructed part, but have not caused any disorder.

Of the mesenteric canal, it may be useful, as well as curious, to remark, that we have always found its state of health or disease to correspond with the appearance of the coat: when this is smooth, the former is full and free from obstructions; when rough, the contrary. In hide-bound, this canal is yellow; in farcy, red, as well as the bowels; these appear blueish, when the horse dies in consequence of being worn out, though, at the same time, the flaccid lacteals still preserve their healthy white, if no other cause to the contrary prevails. But,
upon such further particulars as are connected with the subject of digestion, as influencing or being influenced by respiration and circulation, we have already spoken pretty much at large; see Index.

The liver with its sweetbread, and the kidneys, being liable to certain diseases peculiar to each, besides the property of readily affecting one another by reason of their contiguity, as well as their joint function of refining the blood, next claim our undivided attention. We will, therefore, proceed at once to a brief description of the uses and functions of each, and accompany the same with a few remarks on the present received mode of treating the disorders that impede those functions, reserving particulars regarding the causes, symptoms, and method of cure, to a subsequent part of the volume. Consult the Index; and read over again section 41. page 124.

52. The liver is a very important and immensely large glandular body of a dusky red colour, almost divided, like the lungs, into two lobes, each having two smaller subdivisions; and is attended by its pancreas or sweetbread, a small flat part thereof, which has the property of secreting a sweet kind of saliva. This secretion was noticed before, as entering the gut near the stomach, along with the bile from the liver: both are, therefore, conveniently situated underneath the stomach and behind the midriff, to the skirt of which the upper part of the liver is attached; but the exact functions of this pancreas, or its diseases, are no farther known to
us, except that it partakes a good deal the appearance of its joint neighbour, and that it is indeed *sweet* to the palate when eaten.

Before he proceeds farther, the reader had better consult the plate of a *skeleton* as to the situation and extent of this important organ (important in a *curative* point of view), as relates to the midriff, stomach, and kidneys, where it will be seen included between the squares marked H—M, as intersected by the *lines* numbered 23—30. The side view therein presented is necessarily the left or *near* side, but the other lobe, or right one, is of greater length and more substance; it touches the right kidney, and its upper surface is contiguous to the diaphragm, which presses upon it at each inspiration of the lungs. This tendency of the liver to the right side, seems to have been designed by nature to counterbalance the leftward position of the heart, and of the lower part of the stomach; the *pylorus* or lower orifice of which is seen at the intersection of the lines K and 26. In a former page (*sect. 27.*), we took occasion to describe the minute glands with which the external parts, or solids, are furnished, and to advert to the secretory glands, all which are formed by *arteries* that deposit their contents therein, and which deposit is again taken up into the veins; but the liver, the largest of all glands, and a secretory organ, differs from the others in one great and signal respect: it is formed of an assemblage of veins only. *Its* structure, in other respects, is much after the same principle as that of the minor glands.
Into *the liver* is brought the blood which has been sent from the heart to circulate and nourish the whole system (except a portion which the kidneys attract); a service that is performed by means of a great blood-vessel they call *vena porta*, that passes along the right side of the spine. In size very large, and always filled in health, a sight of this vessel shows how busily employed the liver must be, in separating from so great a quantity of blood the bitter qualities it has obtained by having passed through the animal's system, and imbibed whatever might there lurk of the offensive, the diseased, or the infectious. It proves, also, that any disease with which it may be attacked, must be proportionally violent in its progress, and tedious to cure, inasmuch as both will depend upon the state every other *viscus* and secretory organ may be in, through which the blood happens to have passed. Are the kidneys, or either of them, inflamed? the blood which has recently passed through them comes to the liver to get rid of its noisomeness, in the form of *bile*. Is an *abscess* to be dispersed, and the acrid matter driven from the part to be taken up by the lymphatics? (see section 29.), at the liver it is strained off, and here must be imparted a portion of its baleful qualities in the form of *bile*. It follows of course, that whatever medicine is directed towards the liver must go thither by means of the circulation, *i.e.* through the absorbents: for *schirrous liver* this is best accomplished by the lymphatics; for *inflamed*, or rather enlarged liver,
by means of the lacteals; in other words, these are the internal and the external modes of exhibition, and the preparations of mercury are here mostly kept in view.

The secretion of too much bile, and the consequent inability of the vessels to carry it off, it may easily be foreseen would be the harbinger of jaundice; and its approach may be discerned by the yellowness of the eyes, by the increased number and thinness of the animal's dungs, and the constant emptiness of its belly, which both feels and appears loose and flabby. On the contrary, too little bile must leave the intestines without the requisite stimulus to expel their contents, which, soon getting dry and hard, a constipation usually follows, that defies the remedy by purgatives: nor is the mainful operation of backraking, with the use of clysters always of effectual service, but requires purgatives in their mildest form. Whichever extreme affects the liver, the patient becomes weak: but in case of deficiency, though he may look more brisk for a few days, stretching his hind legs out when unemployed, he afterwards becomes feverish, hot under the tongue, sluggish and dull in the eyes. Scirrhous liver—a corrosion or induration of its fine surface, accompanies this deficiency of bile, and when it recurs often, the disease becomes permanent; but whether caused by, or causing the same, we are yet unable to ascertain. Ulcerated liver is occasioned by a too great heat in this organ: if occurring upon its thin extremity, the disorder cures
itself by a natural operation, i.e. by adhesion to the gut, and passing off by stool; but when seated higher up, it terminates fatally, by wholly debilita-
ting the system, and sooner or later consigns the patient to the knackers.

The preparations of mercury, before alluded to, act variously upon the system, according to the mode of exhibition the practitioner may adopt: in the form of calomel it assists the liver to discharge its functions by lowering its tone; corrosive sub-
limate rubbed into the glandular parts (of the thigh, &c.) finds its ready way to ulcerous and all other affections of the liver's surface, by increasing the secretion of bile; the blue pill (pilul. hydrarg.) is finely adapted to solve the crudities of stomach and bowels in carnivorous animals, but has never been extensively tried on the horse. For any disease of the whole system, or "bad habit of body," as Richard Lawrence properly calls that predisposed state of it which ultimately produces tumours, grease, fistula, farcy—mercury, in its various shapes, is the only specific.

Too great a secretion of the bile, although it pass off, produces a roughish meagre coat, first about the belly; the patient becomes languid, especially after being compelled to any great exertion, when he perspires too readily on the carcass, his manner is uneasy, and after a while, partial hide-bound commences under the chest. Should the bile be of a less acrimonious nature, those symptoms are then perceptible lower down (i.e. farther back), and
when his eyes appear yellowish, it is then a confirmed jaundice; but in very bad cases, producing death, people vulgarly call it "broken-hearted," because commonly brought about by bad usage.*

Inflammation of the liver, which is indicated more by its enlargement than by increased action, generally accompanies those appearances; but we cannot be certain, though it is to be presumed, that inflammation of the part is always consequent upon an over-quantity of secretion. After much procrastination, medicinal remedies are of little avail when tried on the most extensive scale, although no disorder to which the horse is liable is easier of cure, if it be taken in time: the patient requires only a treatment directly the reverse of that which brought on his ailments, and he gets well, almost of course. Regular work, moderate feeding, and tolerable behaviour, comprise these natural remedies: they are usually found efficacious in the earlier stages of the disorder, and then only. But those natural remedies being neglected, and alteratives (the assistants of nature) never thought of, languor of the whole system prevails sooner or later, and the best of medicines fail to act by reason of that languor. The absorbents are then accused of not performing their function properly; or, if they do so, then the

*Since writing the above, we have ascertained upon the view, that a horse, rankling under the effects of maltreatment, absolutely broke the cells of his heart through high-spirited chagrin. The case is described at large in the "Annals of Sporting" for July 1822, under the title of "Broken-heart."
liver and the kidneys fail in refining the blood sufficiently, so that, at its getting to the extremities once more, those particles which ought to have been carried off are there deposited, and form the nidus of those external maladies that are mistakenly considered local diseases, and treated as such, instead of correcting the foul habit of body which is thus plainly indicated.

53. The kidneys, although the seat of only one acquired disorder (inflammation), yet they are so intimately connected with the cure of other diseases, which are constitutional, that a right knowledge of their functions cannot but prove highly serviceable to the judicious administration of the universally approved method of cure, by the urinary passage. Diuretics are so constantly in the hands of grooms and others, that we would admonish them thus early to reflect a little on the consequences of going on, from day to day, in urging these fine glands to over-exertion, whereby they are kept in a constant state of irritation, are rendered incapable of acting their part, or literally become rotten. Of the whole series of tumours or abscess, grease is the only one which people in general think of taking up into the system; the matter that proceeds from the pustules that form grease is so palpably composed of urea, or the principle of urine, which ought to have been attracted to the kidneys, that every body who would cure the grease, very properly, as if by instinct, administers diuretics; and when this means of cure is adopted early,
always with a proportionate degree of success. But torpor, or inaction of the kidneys, usually accompanies grease in its first attack, if it be not the immediate cause thereof; though, when the animal gets old, and has been long time suffering grease, its continuance may be owing to the inaction caused by rottenness or entire loss of the function of secreting urea. In the first case stimulants—alkaline and resinous substances, might effect good, in the latter case they would do harm.

The kidneys are situated, one on each side of the spine, close to the last two ribs (as exhibited on plate 1, at H, I, intersected by figures 28—30), where they are attached as well by the blood-vessels which belong to them, as by stout cellular membrane which covers them underneath. With this exception the kidneys of horses seldom have the covering of fat, termed suet, which we find in other animals, owing, no doubt, to the very great action of the parts. Mr. Richard Lawrence must have been thinking on the ox or sheep’s kidneys, when he wrote his 289th page. For our part, so little of this fat on the kidneys has been noticed by us, that this book was already at press before we were convinced they were ever covered; and yet we have assisted in opening and noting the state of as many horses, we believe, as any men in England who ever wrote a line on this subject. The left kidney lies close to the ribs; the right one farthest forward, is loose, and is connected with the right lobe of the liver; which being much longer than its left lobe, seems
to extend itself backwards for that purpose. Mutual excitement, no doubt, is the intent of this connexion; and that apparent deviation from her true system, which nature allows in the effusion from one part to another, takes place, when either the one or the other may be diseased, obstructed, injured, or destroyed. On no other grounds can we account how it is that brute animals so long survive the total destruction of some vital part, as we frequently find. One consequence of this loose situation of the right kidney is, that inflammation generally makes its appearance upon it earlier than on the left, a circumstance which is partly derived from its proximity to the liver; it also imparts some of its own feeling to that organ, when inflamed; two facts these which ought to be well kept in mind, when we wish to excite unusual secretion in either. In shape, the left kidney approaches the angular more than the right one; from which we infer that, although the functions of the two must be so nearly the same, in affections they differ; at least, we know that a gall or slight blow will affect the left much sooner than the right kidney.

54. The section of a kidney,—which should be performed lengthwise,—will show in the centre its pelvis, in which the tube (or ureter) that carries off the water to the bladder takes its rise: in this pelvis stone is sometimes formed, that often finds its way to the bladder, unless it remain in the ureter, or comes away entirely*. The ureters communicate

* We were called in to examine a horse suffering under the latter
immediately with the bladder, and the water they convey is formed by the outermost red part of the organ drawing the blood into it, and through which it is filtered by the vascular or whitish part which lies next within side; here numerous little tubes convey it to the centre one, or ureter, that enters the cavity of the os pelvis at the conjunction of H. with 34, on the plate of a skeleton, where the bladder is situate, which receives the water.

The blood, which has been so filtered of its urine, is absorbed by a vein, which is plainly visible in the section of the kidney; and the whole function shows how rapidly circuitous any medicine must act, which being poured into the stomach is found, in so short a space as two or three hours, to cause, whose diseases had baffled the skill of many clever farriers. He had been long declared to have "a complication;" that is to say, none knew his disease, for he occasionally voided blood with his urine, in great pain; they had, therefore, given him diuretics to such an excess, that he could not bear the hand's passing along his back over the kidneys; his sheath showed signs of oedematosus swelling, and upon that region being touched he became unruly. However, we saw enough to ascertain, by the heat and tension of the part, that it was inflamed; and, as his pulse was high, his tongue hot and dry, it was proposed to bleed him, and to foment the part; the operation, however, was scarcely performed when its owner resolved to take no further trouble, and the horse was slain. On examination we found his kidneys were rotten, and as pervious as dough; ulcers appeared upon both lobes of the liver, and the neck of the bladder was inflamed a little. The sheath preserved its size; and on the top of the penis a small angular stone, the cause of all this mischief, lay buried under the cuticle; and would, it is apprehended, have come away in the course of a day or two spontaneously. Its weight might be 10 grains. How it got there is most inscrutable.
have worked its passage through the bowels into the lacteals, thence through the heart and arteries into the kidneys, filled the bladder, and caused a staling of the noxious water, which is to carry off disorders of one sort or other. Here it is worthy of remark, that the operation of internal medicines is much more certain in the horse, when directed against the absorbing vessels and the kidneys, than when intended to act chiefly on the stomach; for, as hath been observed, his stomach being one half of it insensible to stimulants, we are not certain of producing upon it any effect whatever. In all swellings of the legs, the good properties of diuretic medicines may be discerned almost immediately, by reason of the connexion which subsists between the function of the lymphatics and that of the kidneys; by a similar mode of operating, diaphoretic medicines no sooner excite the lacteals to a performance of their function, than the skin shows evident signs of its good effects. But both means of cure may be abused, as I shall show more particularly in the sequel: the first, being administered too often, wears out the functions of the kidneys; the second, being carried on too long, at length ceases to act upon the skin.

55. An idea respecting the deposition of water in the membranes was thrown out in the twentieth section; and another, as to variation in the proportions of urine and perspiration in summer and winter, at the bottom of section the twenty-second, to which the reader may refer. On this topic a
foolish notion having got abroad as to the small quantity of *acrid matter* contained in the *urine* of the horse, induced Dr. Thomson* to submit a portion of it to chemical analysis in order to decide that point. "The result was, that it was found to contain an unusually large proportion of that principle, so that without being concentrated by evaporation, it yielded crystals of *nitrate of urea*, very readily on the addition of nitric acid." This fact being thus satisfactorily ascertained, accounts for the strong ammoniacal vapour of stables that affects the eyes of the attendants, and being inhaled (as said in section 39.), is clearly the harbinger of

* Of Edinburgh, in his Annals of Philosophy, for August, 1820. By the way, on this subject it is worthy of remark, that for several years past, the French and Italian doctors have made a great fuss about this *Puree* (urea), or proportion of the principle of piss, calling it "a discovery;" whereas our own people, in every branch of medicine, have been acting upon the same doctrine for better than forty years, to our certain knowledge. Some have regulated their practice (human) by the *appearance* of the water, with various success; and I have a great notion, that this test of the state of the *horse's* health may be added to those other symptoms by which we endeavour to ascertain the ailments of an animal which nature has forbidden to complain. Whatever practitioner should undertake to judge of the horse's diseases by its urine, must prepare himself to undergo a good deal of ridicule, and may expect some calumny; he would not, however, be far from the right path towards making a proper estimate of the quantity or violence of its ailment, though he might not so readily ascertain the precise nature of the disorder. The terms "*nephrin,*" and "*uric acid,*** the oldest and the newest for the principle of this evacuation, show the assiduity of which it has been deemed worthy, in that *practice* where it is confessedly of less importance than it is in ours.
several diseases in the horses confined in them—glanders among the rest.

56. The bladder, or receptacle for the redundant water of the whole system, as it is separated from the blood by the kidneys, is situated within the hollow of the *os pelvis*, at the intersection of H with 34 on the plate of a skeleton, with its outlet or neck turned towards the place of exit, varying a little according to the sex. It consists of three coats or layers, (see fig.) the outer two being muscular, and having their fibres crossing each other—(as may be seen upon splitting it asunder, being most apparent), in a *stale* bladder, the better to enable it to contract upon and expel its contents. The inner coat is membranous, sensible on distension, and secreting an unctuous or *mucous* fluid to protect itself against the stimulating effects of the urine. When, however, the bladder becomes full, the secretion is insufficient for its protection, and extreme irritation ensues, in order to induce the muscular coats to concur in the expulsion of the urine. This desire must be very great in the horse, for the reason assigned at the close of the preceding section, and shows the necessity of permitting him to *stale* upon his first intimating an inclination thereto. The shape of some horses' bladders differs a good deal from that of others,—particularly about the neck, those of the female being always considerably wider, and shorter,
than those of the male; a circumstance to be remembered when we come to treat of the disorders incident thereto, since in inflammation of its neck, for example, in one sex we are obliged to have recourse to instruments, in the other, the urine may be discharged by the fingers. But it so happens that horses are more liable to the disorders just named than mares, by reason of that very circumstance—namely, the length of the neck. The reader will also please to notice, that the thin membrane (termed peritoneum, see page 140), which defends the whole intestine against the friction of the surface, reaches backward to only about half way over the bladder; so that it offers no obstruction to our operations upon its neck in cases of disease, but rather contributes to the expulsion of the urine; as it does also to promote disease of these organs, whenever the said peritoneum being inflamed and thickened ["inflammation of the intestines,"] it then presses hard upon the fundus or bottom of the bladder, which, in the living animal, lies forward, and thus compels the neck to collapse, to get into folds, or to become inflamed. See "Urinary organs—diseases of," in Index.

57. To recur once more to the subject of a preceding section (the 55th)—the principle (of urea) that resides in any given quantity of urine evacuated by the horse, it may be here observed, that when the animal, on a journey, has been pushed onward, and thus prevented from staling for a considerable time, he at length produces it of a deeper colour
and less in quantity than usual; a change which has been effected by the great heat of his body having taken the water up again, by the absorption and effusion which nature has provided, of aqueous particles from one part of the system to another. The principle, or urea, however, remains in the bladder, and produces one of two evils; either the inner or sensible coat becomes irritated, and loses, after an attack of diabetes, some part of its function of secreting the mucous fluid for its defence, if it does not terminate fatally; or, being less severe, but often repeated, a deposition of earthy particles takes place, which the great heat of his body in time converts into stone or gravel.

Palsy of the bladder is induced from frequent repetitions of thus neglecting the calls of nature, as well as from injuries of the spine; in both which cases the nerves having lost their sensibility, the coats do not contract sufficiently, and some water is always left behind. In all diseases of the bladder, a disposition to fill speedily manifests itself; and in palsy, this is the leading symptom. When this evil takes place, the horse, while staling, seems unwilling, or is incapable of discharging the last drops of each voidance: and, if the usual practice of giving strong diuretics be adopted, the animal is thereby ruined, if he does not burst the fundus of the bladder and die immediately: rather, the contrary method of discharging, instead of filling the bladder should be sought, and the readiest way to effect this is to introduce the hand into the funda-
ment, which having emptied, the bladder may be felt much distended. In this case, we are told, "too much pressure might terminate fatally;" but by smoothing the bladder gently with the tops of the fingers, from its neck forwards, is usually successful. In fact, we never should have thought of its failing, but for what is said in one of the books on diseases of horses (White, vol. i. p. 121), where we find a good number of pages bestowed upon "suppression and retention of urine," which are not diseases in themselves, but the effects of disease; the first arising in defective secretion of the kidneys, the second in the bladder, or its neck. At all times, a portion of sympathy exists between this organ and the kidneys, and more between the kidneys and liver; inflammation of either being soon communicated to all three, in a degree proportioned to the animal's general state of bodily health previously to the attack. But it is of the neck of the bladder we now speak, and of its sphincter particularly, as being liable to inflammation; the bladder itself never contracting that disorder, so far as we can ascertain after much patient attention, although it may suffer when disorder prevails in the contiguous parts.
CHAPTER III.

General observations on the animal system of the horse, with reference to the origin of constitutional diseases: recapitulation and further development of veterinary practice, upon the principles before laid down.

Studious reader,—Seeing that a recapitulation of the preceding chapters, and a few general observations arising therefrom, would be necessary, before we examine into the particular diseases to which they have reference, we shall here add the notice of such minor parts of the horse, as may seem to have been overlooked; and then draw such conclusions from the whole, as to the principles upon which veterinary medicine may be most successfully conducted, as appear to us best adapted to your acquiring those just notions of the theory that lead to favourable results in practice.

The animal system* (which has been so often mentioned), whereby life is continued and strength renewed, diseases are contracted, and the disposition to throw them off is constantly manifested, and by which the ordinary wear-and-waste of the various

* A system is a course of action, according to some known rule or law of nature; and the term has been applied to some of man's contrivances also, not very happily.
component parts of the body is unceasingly supplied with new and healthy matter, has been shown, in the foregoing brief account of the separate parts that contribute, by their united actions, to make up this system. A system that, although apparently complex and infirm, is, in reality, simple, magnificent, and robust. It is we (mankind) who derange the due action of those parts, by our vanity, our wants, and self-will; or, by our ignorance, put the whole system out of repair, when we endeavour to control Nature, instead of humbly following her track, and working after her fashion; and every mechanic knows, that a system, or a machine, being once put out of order in its minutest part, incurs the danger of complete disorganization in those that are more evidently material to the performance of its functions as a whole: an observation that applies as well to a watch or a steam-engine, as to a worm, to man, or the horse; but which, of course, it is our intention should be applied to the last-mentioned animal particularly.

Our Creator, however, as if prescient of the barbarities his image would fall into, in the exercise and abuse of the power he gave us over the living things of the earth, hath, in his goodness, conferred on brutes the means of supplying from one part of the system the losses which accident may occasion in another part: a subject well worthy our patient scrutiny, as furnishing the means of effecting cures in desperate cases, and not to be disregarded in first attacks of malignant diseases.
But, "the animal system," as a term, or in fact, may be taken to imply as well that of all animals as particular kinds of animals—descending sometimes (not improperly) to individuals of those kinds. Some persons, however, descend still lower, and the term "system" has been sadly misapplied, and bandied about from one thing to another, until it is brought to describe particular parts or portions only of the individual's system. That of the dog kind, the horse kind, and mankind, are good and proper distinctions, for the system of animal life differs in all three: they are not in every case moved in a similar manner by the same class of medicines; whereby we first perceive that their systems differ, and we examine the dead subject of either kind (as in the preceding chapter), to find out how this takes place, and in what degree, and we regulate our practice conformably to the discoveries so made. The several individuals, too, of the same kind, have particularities in their respective systems, arising from habit, from country or climate, or from crosses*, that demand our serious analytical reasoning, in the application of similar remedies, and adapting their proportions to the removal of similar symptoms. Thus it is, a sensible difference is known to exist between the constitution of a cart-horse and a blood-horse, between a galloway and a hunter; each requiring accurate discrimination

* The system of the same individual, also, may undergo changes by time; so that a medicine may operate differently at present from what it formerly did.
in ascertaining the state of disease*, and this consideration ought to inspire us with carefulness in employing the most celebrated remedies, since that which restores the one might be injurious to the other. Among those four breeds, we frequently find *individuals* variously affected from the same causes according to their built, shape, or make (see pages 4, 25, and 48), according to the constitution and co-adaptation of the dam and sire: as age may come on, accidents have taken place, or chiefly as the individual may have been mistreated by his unworthy master, the sordid farrier, or unfeeling ostler. To all which important distinctions in the state of his patient's particularities, we beg to call the studious reader's most serious attention, while examining his case, in order to regulate the remedy most appropriately to the *degree* of attack.

Reader! In the two preceding chapters of this treatise, *more* of the animal might undoubtedly have been described, or the same subjects considerably enlarged upon, and more parade of learning might have been displayed, but the reader would not have benefited one jot by that course of proceeding: he might, probably, have bewildered himself (as many do) in the mazes which would then surround him; whilst the description of those parts of the animal, which contribute but inferiorly to

* That surest barometer of health, the pulse, would indicate an approach towards *fever* in one individual, which might be the certain standard of health in another. See "The Pulse," at page 179; and further, in *the Groom's Oracle*, see *Pulse*, in Index.
the system we had in view to illustrate and explain, might have led him to look upon these in a light, too important for the functions they perform—as regards our present purpose.

The eyes, the tongue, the ears, the skin and hair, the tail, the genitals, and the hoof, or foot, though each deserving our most sedate attention, for many good reasons, yet, as they do not originate disease, we then purposely avoided taking particular notice of them*. Nevertheless, we do not mean to deny, that they all, according to each of its functions, accurately indicate the existence of disease, as they do of health, and the degree of both is marked on them with wonderful precision. Hence it was easy to conclude, even though we did not know the fact to a demonstration, that they are subject to some deplorable maladies that are peculiar to each, arising out of constitutional defectiveness, to say nothing of accidents, nor of the fancied improvements man presumes, to make upon the works of his Maker.

Under this last reproach lie all those farriers and others, who give pain unnecessarily to the animal in the indispensable operations. Foremost of these we class those of docking and nicking, a custom that came up among us in England, in the early part of the seventeenth century.

Since the censure that stood in this page was

* The diseases of the foot, we consider as those of accident or infliction, or depending upon other parts of the system; and those, with a brief anatomical description, will form a separate chapter.
published, we perceive that the fashion which accords so much to good taste, has taken a turn again in Hertfordshire, and the more graceful as well as useful long tail prevails, or, at least, the already docked are suffered to become switch tailed.

*Firing* is another of those barbarous practices that is oftener resorted to than necessary or proper. In fact, we may observe that this and similar painful operations are adopted in an exact ratio that the operators’ education may have been neglected. Who, besides they, would *pull* a mane or tail in such a climate as this? Who else than such men would clip the heels of working horses towards the approach of winter?

Of *the foot*, we have already, in the first chapter, noticed some general faults, arising from constitutional defects in the form of the whole limb; and we shall thence be led to enter into further considerations thereof, with more particulars, under the article “Shoeing,” as well as when we come to treat of the several disorders incident to this important part of the frame.

The *skin* and *coat* received some attention under the article *secretions* and elsewhere, as the reader must recollect, or refer to; but he must never forget, that the first mentioned may be safely and powerfully stimulated as the outlet for many constitutional affections of *the system*, the proper time for their use being indicated (as we said before) by the appearance of the coat.
The tongue always partakes of the general state of the system: in the horse, it does not afford to the sight so sure a prognostic of the state of the stomach as in the human subject; but, to the feel, it communicates to us the state of the blood with so much accuracy as demands our assiduous attention, in order to acquire, by practice, the most intimate acquaintance with its monitions. This member of the body, in conjunction with the coat, we have always considered the health-gage of our patients. See observations on the "Pulse" at page 180, and *Groom's Oracle*, Index.

The eye is a most material organ of sense, and is much studied by those who would render themselves good judges of the general soundness or unsoundness of the horse's constitution. It beams bright and steadily in health, projects most fiery when the animal is most vigorous; in lassitude it sinks, it blears with a cold, and, under extreme circumstances is extinguished. After a heat, horses full of blood, with foul stomachs, certainly alter in their vision, shy and become troublesome; and, so sure is the eye the barometer of vigour, that horses got by old sires have the eye more sunken than others, with a greater hollowness over it.

The ears, by their movements, show the apprehensions of the horse, as well as his disposition. When he fears the lash, he turns their cavities backwards. Is he disposed to be resentful, they are laid flat on his poll. Following his companions, or the hounds, or going homewards, the cavity of the ears turn
sharply forward: asleep, as well as under other circumstances of easy watchfulness, one ear turns forward, the other backward; but, when roused suddenly, they alternately change position. Who, then, would destroy these useful appendages of the horse’s organ of hearing? Who would singe off the hairs, which, passing from side to side of the cavity, catch the sounds, and convey to his rider the first notice of danger from wild beasts, as well as pleasure from the cry of the hounds? The wily Arab knows, by his horse’s ears, of the approach of enemies; but the wise Englishman relies too securely upon his own comparatively imperfect hearing, and cuts off those better intelligencers of distant occurrences; or, he more assiduously abridges their utility, by clipping away the inside lining; or, worse still, by applying flame to the part, he renders the horse skittish ever after. These are the only disorders of the ears of horses (and they are inflicted ones, with a vengeance!); if, for want of this hairy defence, premature dulness of hearing, occasioned by rain, dust, and other substances entering these organs, be not another.

That the genitals draw off from the system and store up a noble secretion, for the purpose of continuing the kind, is certain; but we shall pursue the matter no further than to notice the change to which the coats of geldings are subject as to colour, compared to those of perfect horses; and all the inference we mean to draw from that fact is, the still further corroboration of our previously maintained
opinion, as to the seat of perspirable matter residing in the lacteal *part* of the system.

*Finally,* as it is the blood which by its *deposite* forms all those *parts*, so by means of the blood must we endeavour to correct any derangement of the *system of animal life*, whether of quadrupede or bipede; for the working of *the system* in the making of new blood and cleansing the old is the same in all, though differing in degree, whilst mainly agreeing in the process. Would any one demand how it comes to pass, that quadrupeds draw so much substantial nourishment from herbaceous vegetables, whilst man can only extract a watery juice from such materials, devoid of all nutritious qualities? let him be answered, that all depends on the digestive powers, these being greater in the brute than in man. It even appears plainly to us, that the animal food taken by man is the same originally as the herbaceous food taken by quadrupeds, only that it has mean time undergone the process of digestion, sanguification, and deposition in the solids, &c. and hence arises the difference in the *practice of medicine*, we delusively term *the curative art*, as applied to the one animal and the other. Every disease is in fact a compound, varying in different constitutions, and the composition of the remedy should be adapted to every variation thereof, even of the same attack in its several stages.
BOOK II.

THE CAUSES AND SYMPTOMS OF VARIOUS BODILY DISEASES INCIDENT TO THE HORSE; WITH THE MOST APPROVED REMEDIES IN EVERY CASE.

CHAPTER I.

Of Internal Diseases.

INFLAMMATORY DISORDERS, GENERALLY: — FEVER.—From all the information the reader may have collected together in his mind, respecting the "circulation of the blood," as described with instructive minuteness at pages 114 to 123, he will naturally conclude that the horse is ever most liable to contract one or the other of those disorders we term inflammatory. The great heat of his blood, combined with his bulk, and the amazing exertions he is compelled to make, all together constantly pre-dispose him to incur fever of the whole system or inflammation of particular parts, according to concurring circumstances. Nor is the matter changed one whit, when we reflect that fever sometimes terminates in local inflammation, which we term "critical," as being the crisis and termination of the disorder; and that the inflammation of one part
or organ (the liver in particular) frequently devolves into fever of the whole animal system, by means of the rapid circulation of the blood through the diseased organ. *Inflammation of the liver*, however, is not so often indicated by great heat of the part, as by enlargement thereof, visible during life: we recently met with one which weighed nearly four-score pounds, after being parboiled.

Let us proceed to discuss the subject *generally* at first, and to pursue each in detail afterwards; simply premising, that all the disorders incurred by the horse are referable, more or less, to this overheated or inflammatory state of his blood, and its consequent unfitness for the purposes of duly promoting animal life, health, and vigour. For, the more heat, the more viscidity or thickness there will be in the blood, and the less will it be found capable of circulating the longer such unnatural heat continues, up to a certain point of the disease: when the animal is so far affected as to lose its appetite, and consequently no fresh blood can be formed by the digestive powers, the blood then becomes thinner every day, because its more solid particles are constantly being deposited in the cellular membrane to supply the waste that is unceasingly going on there. The reader would do well to read over again what is said concerning this process of the *animal system*, at page 144, with the references there made, to page 116, to page 72, and, in fact, to the whole tenor of the second chapter. But this supply soon fails, as necessarily
it must, when it is not replenished at the source, and wasting of the solids succeeds of course, unless nature is assisted by our art judiciously:—the right application of this art is what we are now going in search of.

One of the immediate consequences of the horse being hard worked, or high fed and physicked with stimulants, is the constant heating or feverish state of the blood. Increased action of the heart and arteries accompany and keep up this state of irritation, which may be further accelerated by the animal's being allowed to take cold whilst in that state, whereby the perspiration is checked of a sudden, and the blood which may then fill the smaller vessels is detained there, to the further annoyance of the larger ones: he then contracts inflammation of all the solids and organs of life, or, more properly, fever. But, when only a certain part of the system, or a single organ is thus checked, we consider the affair under the name of inflammation of that part, as of the lungs, the kidneys, &c.; always keeping in mind, that by continuance, these extend their baleful affections to other organs, with which a certain sympathy is known to exist. In like manner, when external muscular parts swell and secrete matter, this is also considered as inflammation of that particular part—or tumour, or abscess, with a great variety of names, according to the place where it may be seated: poll-evil and fistula are among those external complaints to which we allude.
The latter, or *local* kind of inflammation, is the effect of the former, or continued internal fever, with its concomitant unfitness for the purposes of life; and whenever such a tumour or abscess makes its appearance near the surface, the general inflammation or fever subsides; when it discharges offensive *matter*, the fever is cured. If such a tumour appear without previous general fever of the system, we *repress* it, so that it may *disperse* and pass off by stool. It may usually, however, be considered as an effort of nature to relieve itself of offensive viscid matter that lurks in the system; and in this case only, when well ascertained, would that reduction of the system which we shall shortly insist upon as proper in all inflammatory attacks, be least advisable; as nature would then require aid to assist her in her efforts, rather than subtraction from her powers, by the bleeding, purging, &c. so recommended.

But whenever a *cold* is caught, whereby the trunk is affected, one of two evils is experienced that is quite contrary in its effects: 1st, Either the bowels lose the power of retaining their contents, and of contributing their aid to the purposes of digestion, chylification, and sanguification, *i.e.* the making of *fresh blood*, and diarrhoea ensues; or, 2d, The extreme heat of the body causes the dung to harden; the stomach then throws up its fumes to the head, and if the obstruction be not speedily removed, the most distressing consequences usually ensue. Either extreme may come on gradually and imper-
ceptibly; but as the latter (termed *constipation*) is of most frequent recurrence, is a disorder of repletion, producing vertigo, staggers, apoplexy, megrims, or fits, we have considered it under a separate head, as "costiveness;" seeing that it sometimes supervenes without previous fever, though always accompanied by it. One or other of these species of affection of the bowels is also produced by *catarrhal inflammation*, or fever of the organs of respiration, when this is violent or of long continuance, or the patient is *bled* too much.

Respiration of confined or noxious air in close stables, as described at p. 120, also occasions quicker circulation of blood; this is *temporary fever*, and occurs almost every night in some stables, which may be confirmed by sudden exposure to the open air, and the consequent detention of blood in the small vessels we term *capillary*; but usually goes off by natural perspiration before morning. Sudden immersion in cold water, whilst sweating and resiping with difficulty after a *run*, wading through a river, or standing in a current of cold air, are all prolific sources of inflammatory disorders. Indeed, fever and inflammation are so closely allied to each other, that we run little risk of creating confusion of terms by considering them as derived from the same origin, and none whatever in treating of both in the same chapter. For most stablemen and farriers, as well as many veterinary writers, do speak of the one and the other promiscuously, as if they were the same, when describing the symptoms
of either; nor do we see any good cause for deviating from this practice upon the present occasion, after the slight distinction just drawn.

One other general observation may be aptly made in this place, which may stand instead of much discussion hereafter. As fever is a necessary consequence of any inflammation whatever, so without fever there would be no inflammation. Every run you give a horse heats or inflames his blood, quickens his pulse, and he sustains temporary fever. Whilst in this state, if any viscus, or organ, that constitutes a vital part of his system, receive such a check or damper as we have described, obstruction of the finer blood-vessels ensues—as, of the lungs, by their drinking cold water, or mere affusion of it on the chest, and inflammation is its name: if the whole body of an animal or its entire surface be so affected, the evil consequences are similar, and fever is the name by which we designate it. Horses out of condition, or already in a low state, though feverish, with quickened pulse, do not require further reduction; since this is evidently "low fever," which we have treated of under a separate head; as we have also "Typhus fever," or that affection of the whole system which arises from a vitiated or very corrupt state of the blood. But, in all cases, the best guides to the practitioner for his prescriptions, and indeed all his operations, are the causes, the symptoms, general health and peculiarity of constitution of the animal; when it so happens that such particulars can be extracted from
those about him, as will be the case in all studs of a superior cast. If the feverish affection arises from inactive kidneys, the diuretics recommended under that head will be all the treatment that is requisite in such a case; if a dull heavy pulse and the state of his dungsings show that the bowels only are at fault, purgatives alone will restore health. So of any other visceral obstruction, when these give pain, fever ensues, and is best removed by the exhibition of mercury; if the internal irritation continues, rowelling is the remedy most appropriate to such cases, and the state of the pulse will tell the doctor when and why he should bleed. This will bring us to an early consideration of "the pulse," its indications, and general rules. In all cases of inflammation, whether of the whole system, or fever, or of particular organs, let bleeding be resorted to immediately, in quantity proportioned to the amount of heat, which is ascertained by the temper of the pulse. "Open the prima vice," also, is a good maxim of a late respected lecturer on those subjects, meaning thereby—purge the bowels or chief canal, and keep them open. Copious clysters of warm water-gruel assist the latter materially, particularly if a solution of salts be added, according to the nature of the case; but rather than delay the clyster through want of the ingredient being at hand, use simple warm water only. Very often, in slight attacks, the animal requires no other treatment, if resorted to in time; but delay is dangerous; for, with every hour the symptoms increase in a
three-fold ratio, and the animal becomes weaker and weaker every moment, and, therefore, less able to bear up against the attack. In all cases, be quick, for ruin is going on with rapid strides, whenever the animal shows signs of great internal pain. Fresh air, diluting liquids, and clysters, in all cases of inflammation whatsoever, are found of as much service in the restoration of health, as the best active medicines that can be administered; the first mentioned most positively so, unless the animal perspire greatly at the time, or it suffers under a fit of shivering. Danger is to be apprehended in the latter case, and the fresh air need not then be admitted; but if shivering is succeeded by sweating, or even a small degree of moist heat, it may be considered as the crisis of the disorder, when we may conclude something has taken place that is favourable to the cure—of which more particulars in the proper place. Continual shivering, by the way, denotes the termination of all inflammatory diseases—in death; cordials in such cases may do good, but more frequently accelerate the catastrophe; whilst the comfortable diluting liquid—water-gruel, will afford relief in some measure, and can do no harm. But when the symptoms abate, fresh air, that issues not in streams, is, of all other restoratives, that upon which we place the most reliance; even removal to a fresh stall, or up and down the stable, effects great changes in the animal's spirits, that cannot fail to strike the eye of an attentive observer,
and bespeaks, more than words can convey, the vital necessity of a cool atmosphere.

The Pulse—Being the chiefest criterion for judging of the state of the circulation of the blood, and as we have sat down with the notion that our book will be read straight-an-end at first, let the reader attend a moment while we say a word or two on this preliminary topic. Without an accurate knowledge of this touch-stone of the main spring of life, no one can form a judgment fit to be acted upon as to when it is necessary to bleed, nor of the quantity to be taken: thus, in cases of fever, the groom begins very properly by bleeding; but he almost invariably takes too little, or in case of increased action of the pulse, through over exertion of the animal's powers, he bleeds when such a course is detrimental, and almost always administers cordials, thus reducing with one hand, and increasing the action with the other.—See pages 114, and sequel.

When in health, the pulsations or strokes are from thirty-six to forty in a minute; those of large heavy horses being slower than of the smaller breeds; and of old ones, they are also slower than of young animals. When a horse of either kind may be just off a quick pace, the strokes increase in number; as they do if he be alarmed, or terrified, or hear the hounds' familiar cry. Fever, of the simple or common kind, usually increases the pulsations to double the healthy number; hence the necessity of grooms ascertaining the state of this
index of health, while the animal is still free from disease, goes to prove over again the propriety of our plan of teaching the curative art in animals, by closely examining the indications of health, and setting down in one's mind every deviation therefrom as the approach of illness, that ought to be met and combated at the threshold.

In this view of its utility, why might not the attendant groom, or horse-keeper in more humble establishments, keep a register of the state of every horse's pulse, when it comes first under his care, and renew the same examination at intervals of a week or ten days? This practice alone would render him expert in all cases of imminent danger; to say nothing of those other indications, the dungings and the water voided. On this latter point the reader will turn back to what is said of "Urine" in page 156.

As the fever increases in violence, likewise, when the animal is in great pain from inflammation of the intestines, &c. the pulse beats still higher, and reaches to 100 in a minute, or more. The danger is then great, and less than three or four quarts, drawn from a large orifice, would do harm rather than good, by increasing the action of the blood, and the hardness of the artery would also be increased. To ascertain either state, the attendant should apply the points of his fingers gently to the artery which lies nearest the surface. Some prefer consulting the temporal artery, which is situated about an inch and a half backward from
the corner of the eye. Others again, and they are the greater number, think it best to feel it under-neath the edge of the under jaw-bone, where the facial artery passes on, under the skin only, to the side of the face. This edge, or angle, of the jaw-bone, will be found in our frontispiece, at the point where the line E is intersected by the line 5. In either case, too great pressure would stop the pulsation altogether; though by so trying the artery against the jaw-bone, will prove whether it be in such a rigid state of excitement as attends high fever; or elastic and springy, slipping readily from under the finger, as it does when health prevails and the strokes follow each other regularly.

The presence of high fever is further indicated by a kind of twang, or vibration, given by the pulse against the finger points, resembling greatly such as would be felt were we to take hold of a distended whipcord or wire between the fingers, and cause it to vibrate like a fiddle-string, sharply; whereas, in health, a swell is felt in the vibration, as if the string were made of soft materials and less straitened;—facts these which owners would do well to ascertain by practising upon the pulse of their own horses. Languid or slow pulse, and scarcely perceptible in some of the beats or strokes, indicates lowness of spirits, debility, or being used up: if this languor is felt at intervals only, a few strokes being very quick, and then again a few very slow; this indicates low fever, in which bleeding would do harm. Quickness, however, is the chief indication of
the whole class of inflammatory fever; and this being our principal object at present, let us postpone further consideration of the pulse until we come to treat of "blood-letting."

FEVER.

There are two kinds of well-marked fever, simply so called—first, that which arises from the pain an animal may be put to by the derangement of some main organ of life, by misusage, hard riding, wounds, &c.; and, secondly, that which consists in a general inflammation of the blood arising from a cold, a chill, or sudden check, as before described.

To what is there said, let us here add, that another prolific cause of fever, as well as inflammation of the lungs and of the intestines, is ascertained to have been brought about by putting horses into hot stables after long exposure to the air, when this is sharp or frosty. An effect that is thus accounted for: the suddenness of the change from cold to heat, occasions the blood in the capillary vessels to enlarge, first, (heat occupying space) whereby the blood, unable to get back into the larger vessels, finds its way out of them, and as is seen in the human patient, reddens the part affected by its heat. If this suffusion be general, fever ensues; though the part commonly affected is the respiratory organs—the nose, the throat, gullet, or lungs, sometimes the whole together, and we then term it catarrh. A cold in the head, is the mildest
symptom, with blear eyes, and a running at the nose, which may devolve into glanders if the discharge be from one nostril only, and that one the left. A good vulgar criterion for judging when a stable is thus over-heated—if common-sense and the number of horses already in it be not sufficiently intelligible—may be deduced from the behaviour of the horse himself; on being brought to the door, he will refuse to enter it without compulsion, or at any rate, if hunger impels him, he hesitates to comply for a moment.

The ancient vulgar name given to this alarming disease conveys to the common observer a better idea of its force and danger, than those which are settled by consent of the faculty of horse medicine; and the phrase "inflammation of the blood," may be taken as more plainly indicative of the cause of fever than aught the moderns have substituted in its place. Had our plain-speaking ancestors termed it "inflammation of the blood-vessels," they would have been still more accurate, probably; but no mistake is more common in the avocations of life, than to speak of the thing contained by the thing containing it, and the contrary. When the symptoms come on quick or acutely, the most prompt measures must be taken: a mild attack may be easily reduced, if taken in time, but, if neglected, it assumes the most alarming symptoms. Evacuations and diluting drinks are the proper means of reducing the patient; but before purgatives are administered, see what is said a few pages onward respecting "Costiveness;" for it not unfrequently happens, that this is all that
ails the animal, with the addition of his being worked too hard while costiveness is upon him.

In either case of accelerated pulse arising from those causes, bleeding should presently be had recourse to, and let the quantity taken be regulated by the force and quickness of the circulation of the blood; for this is what constitutes the fever. If the pulsation advance to above 60, two quarts should be drawn; if above 70 in a minute, three quarts of blood would not be too much to take away at once. If the number of beats be much more, ascending rapidly, with the rigid feel of the artery above described, four quarts at least must be drawn, and that from a large orifice. Should this rigidity, or hardness of the artery continue, notwithstanding the bleeding, a quantity that shall cause faintness or tottering might be taken, or perhaps a repetition take place of the same operation in greater quantity, until that hardness in the artery is no longer felt. Some skill, derived from practice, is required in watching for this last-mentioned symptom; but whatever is to be done, let there be no delay in the first operation: twelve hours should intervene between the two bleedings, if a second be necessary.

Immediately hereupon, let a mild purgative be administered, adapting this, as well as the amount of bleeding, to the size of the horse, if he belong to either extreme of exceeding large or very small. If costiveness prevail give a bran mash previous to the physic; or before bleeding, provided it can be got ready in time. For one of the moderate coach-horse kind give the following
Purgative Ball.

Aloes, 7 drachms.
Castile soap, 4 drachms.
Aromatic powder, 1 drachm.
Oil of caraways, 6 drops.
With mucilage sufficient to form the ball for one dose.

In all cases of fever arising from accidents, hard runs, &c. which may be considered as temporary excitements only, the above treatment in its mildest form will be found sufficient completely to reduce the symptoms; but in the fever, simply so called, (arising from inflammation of the solids as before described), repetition of the purgative becomes necessary, with mashes, a quiet stable, and an attentive groom. When the fever arises from repletion, indigestion, or any derangement of the stomach or large guts, its immediate cause will be found in hardened feces; but back-raking should only be avoided if the fever has made some progress, and in addition to the forementioned remedies, give a

Purgative Clyster.

Water gruel 6 to 7 quarts.
Table salt, an ounce to each quart.

Let it be administered assiduously, and some assistance be given to bring away the first hard feces that presents itself: the remainder of the hardened dung will come away, naturally, in good time. See further under the head "Costiveness."
Castor oil, in the quantity of a pint or more, will open the canal partially only, passing by the main evil in the cœcum and great gut*, and producing but a small quantity of the offensive cause of disease. But help must be afforded in this respect; and if the bowels yield not to the purgative ball, other means must be resorted to, though we should never think of relying upon the oil, except in the first instances. Although the constipation or obstruction be obstinate, yet very strong drastic purgatives are ineligible, as they might kill the animal, or at least injure the intestines materially, by reason of that very circumstance: prepare the patient with plenty of oatmeal gruel.

Distinctions have been drawn by some writers between "symptomatic and simple fever;" that is to say, whether the excitement, called fever, originates in a check of the system generally, or whether the feverish symptoms have been produced by some particular inflammation, either internal or external; but, as the treatment in both cases is so nearly the same, we will make no such distinction. The internal attacks alluded to, when confined to a single organ, and not extending to the whole frame, are more properly termed inflammation of

* The practical reader, whilst waiting the progress of the disease, will not waste his time by turning back to the first book, at pages 14, and 123, and see what is said of the conformation of those large guts, and the difficulty of escape that must attend their offensive contents at the turns or sinuses (which we have there considered as so many valves), when inflammation or fever has once begun.
that viscus or organ, and, therefore, will be treated of hereafter, under the following heads, *viz.*

Inflammation of the lungs,
Inflammation of the stomach and intestines,
Diseases of the liver—infiammation, &c.

All these produce *fever* throughout the whole system, when either exists but in a slight degree: for those *parts* are all of them *vital*, and communicate their feeling to the solids by means of *the circulation*. It is not, however, until these attacks are well marked, that they deserve separate consideration; for some horses suffer under the one or the other during life, with more or less malignity according to existing circumstances, the lungs being the most general sufferer, the bowels the seldomest attacked of either, but usually proving the most fatal of this whole class.

*The symptoms*, in all cases, are *heat* and acceleration of the pulse, as before described, and which in fact brought us to the consideration of this portion of our subject before the others. A hot mouth soon comes on; shivering takes place early, and the animal evinces signs of internal pain by looking at his flanks or chest. The fever is then likely to fix on the lungs, if not speedily reduced. Loss of appetite follows; but too *gradually* to be waited for, as a criterion for judging and acting promptly. He will evince languor and dulness, with half-closed eyes, and a small discharge from them, as if tears escaped, sometimes;
this last will happen in cases of mere debility or starvation also, when it is not too much to suppose the animal may be deploring its hard fate. Consulting the pulse, however, will settle any doubt as to which ailment the animal labours under; for this main characteristic of health will, in the latter case, partake of his debility, and strike now hard and then soft, a few beats each: in this case a feed of corn, or water-gruel, would probably restore a more healthful even pulse, whereas bleeding would go to destroy the patient. It has been termed low fever, though not very properly, and lento r, or more accurately lenteur, (i. e. slowness, dulness, heaviness) by the French veterinarians; yet, having at present no better name for it than “low fever,” under that head, we will shortly bestow a few lines on this species of systematic debility.

The dung and urine are always good indications of the state of the body: if the former fail, fever is the cause; which subtracts also from the quantity of urine, and if he stale small quantities at short intervals, some internal inflammation has taken place. [See Inflammation of the kidneys.] In fever, the mouth and tongue become drier than ordinary; and if any saliva be secreted, it is tough and ropy. If the animal be in good condition, upon lifting the eyelid an uncommon redness appears: if he be out of condition, or in a low state, this does not always happen; so that this indication may be reckoned among the uncertain symptoms.

If the remedy and the symptoms of fever are
thus pressed forward together upon the reader's notice, as exemplifying the assiduity he should display in repelling the attack, let him know that his work is but half completed when he finds the heat and acceleration of the pulse reduced by his endeavours to the ordinary standard. The tone of the patient's stomach and the whole digestive process require restoration, and this with a careful hand, that the bowels may not again get overloaded; and for this reason a second attack of this sort would be more difficult to surmount than at first; for the bowels have partly lost their function of expelling their contents, through the violence of the disease, if not by the harsh action of the remedies employed. Hardy working horses, of course, recover their appetite as soon as the fever abates; and no further care is required for such than an occasional laxative or purgative, according to the amount of obstruction. But high-bred horses that have been kept tenderly, and their stomachs submitted to the stimulation of cordials for a long time, their organs of digestion being then more irritable, require more attention in restoring them to their proper tone. Moreover, until the tone of the stomach is completely restored, which is known by the return of the patient's appetite, the kidneys exhibit their ill-feeling by refusing to perform the function of secreting urine—so great is the fellow-feeling between these and the stomach, by means of the vena porta, one of the large blood-vessels, descending. The ball prescribed at page 185 may
be given at intervals with the fever powders; and subsequently, the fever drink prescribed below, for all other descriptions of horse recovering from fever.

**Fever Powder, No. 1.**

Powdered nitre, 1 ounce.
Emetic tartar, 2 drachms.
Mix for one dose.

**No. 2.**

Powdered nitre, 6 drachms.
Camphor, 2 drachms.
Calx of antimony, $1\frac{1}{2}$ drachms. Mix.

If either be deemed more desirable in the form of a ball, this may be effected by mixing the *powder* with mucilage and meal; but in the form of powder mixed with his corn is most eligible, as the medicine then acts earlier, whereas the ball presently descends into the blind gut.

**Fever Drink.**

Cream of tartar, 1 ounce.
Turmeric, 1 ounce.
Diapente, $\frac{1}{2}$ an ounce.
Mix in powder, and add to a quart of warm gruel, to be given twice a day. This is a good cooling stomachic, and restores the appetite, at the same time that the disposition to the return of fever is kept down: if found of marked service, the doses may be extended to three or four times a day, for a week or more.
LOW FEVER *

Together with typhus, or putrid fever, and rheumatic fever, are diseases incident to the horse, though attempts were long made to deny the application of those terms to any of his numerous afflictions, by those who dread, inordinately, the falling into analogies with the human practice; a fear that may be carried too far, notwithstanding all our care should be employed in separating this from the veterinary practice.

Cause.—Of low fever, under the idea of debility, a few words fell on the preceding pages: and truly, if "high fever" may be produced in a subject that is full of blood, or in good condition, by over-exercise, and the other causes thereof set down above (pages 182—188: see also book i. at page 128, &c.), these same causes, operating upon a horse out of condition, or which has not sufficient blood in his frame to receive inflammation, necessarily occasion that languor which attends debility of the entire system. The reader will turn to book i. at page 124, and read over again what is there said as to some causes of low fever. But

* Termed also slow fever, but whether given to designate the comparative slowness of the pulse, or the tardiness of the final catastrophe, is uncertain; but we may observe, that it has another claim to preference, inasmuch as the blood drawn from animals in the low state, coagulates much more slowly than when they are in good health. Such blood is also buffed; thus affording one more proof of its being genuine fever.
the respective terms we give to the various kinds of attack would signify much less than they deserve, were it not for the danger we should otherwise fall into of treating one disorder for another, when the symptoms (some of them) so much resemble each other. This danger is more likely to come upon us in cattle medicine than in the other practice, since we are under the necessity of finding out what is the matter with our patients, whilst the human doctor receives the information at once, in words.

As inflammatory fever is more prevalent in the spring and summer, owing to the high condition of most horses when first attacked, so does low fever, or irritation of the animal system of a horse in low condition, mostly prevail in autumn and winter. We owe this latter in great measure to the debility or weakness brought on by the moulting of his summer coat, when the autumnal equinox sets in. Being then much exhausted by the heat of the season just gone by, he sweats profusely on the least exercise: then his coat becomes dry and husky when at rest, and his skin sticks tight to his ribs, slightly resembling hide-bound. The animal having lost much of his natural covering, and no care being taken to palliate this loss, he is more liable to catch cold if exposed and still pushed in his work. If not relieved from its severity, post-horses in particular become unserviceable in great numbers, to an alarming degree, resembling much the distemper of the spring season. Too often it
happens, such knocked-up horses are considered as *done for*, and the owner sells off; whereas experience tells us, that a nourishing regimen would restore them to their wonted vigour; for the serous or watery part of the blood (book i. sect. 20, 21.) having been drained off by the violent perspiration they were exposed to by their summer work, the muscular fibres become rigid, and the blood too thick for circulating in the finer vessels; it, therefore, remains rioting in the larger ones, distending their capacity and increasing the irritation. Working horses are then usually deprived of their corn, because they cannot work; this only adds to the *irritation* of the vascular system and solids, which constitutes the low fever we are now considering.

*Symptoms.*—Parallels, or distinctive characteristics of such diseases as somewhat resemble each other, are, therefore, very proper, inasmuch as they prevent those dangerous *mistakes* that happen in the human practice as often as in the veterinary. Such parallels are, therefore, particularly serviceable to veterinarians: for this reason it is we recommend the reader to compare what is said of the symptoms of high fever, just above, with the present page, as regards the *symptoms of low fever*. They are placed near together for that purpose, as we then said (at page 174.) The *pulse*, in this case, never mounts high during an entire minute, but beats quick a few strokes, and then slow, and so low as scarcely to be perceptible; this denotes, that though *fever* be present, there is not strength sufficient to
bring it to a crisis. The artery feels rigid at intervals only, and again becomes supple, if not elastic, to the touch; his flanks are agitated more than usual, and his hind quarters and ears become cool if not cold. As in high fever, his eyes are dull and heavy, and water will occasionally fall from them. Though in the former species of fever he evince considerable pain, in this no such symptom appears, but a drooping or despondency assumes its place, with hanging the head below the manger.

Remedy.—Unless his body be already too open, give the laxative draught, as under; and as he will still feed, diuretic powders may be mixed with each feed of corn, consisting of nitre and white rosin, of each 3 to 4 ounces, divided into five or six doses. Should the urine appear turbid, or come off with difficulty, in small quantities, the diuretic ball is preferable; and these, with good gruel and care, succeeded by a course of tonics, will restore to the animal a comparative portion of health. Time and moderate usage will accomplish the remainder.

Laxative Draught.

Aloes and carbonate of potash, of each 2 drachms.

Mint water, 4 ounces.—Mix in water-gruel.

This will correct the urine also; and its laxative quality may be increased by increasing the quantity of aloes.
A Diuretic Ball.

Turpentine and soap, of each 4 drachms, with mucilage and meal to form the ball.

A good restorative for lowness, occasioned by the moulting-fever of autumn, is recommended by James Clark of Edinburgh: he says, "the end of autumn proves very severe to those horses whose flesh and strength are exhausted by hard labour. In this low and spiritless state the moulting season comes on, and carries off numbers that good nursing and feeding, with rich boiled food, at this season, might have preserved. Carrots and potatoes recover some horses surprisingly; it renews their flesh and the fluids generally, and promotes the secretions: it operates upon them nearly in the same manner as spring grass, and its effects are presently visible on their coats." Many stable men give oatmeal mixed into bergue, or crowdie, for horses that evince signs of languor and lowness of spirits, after fatiguing work in winter: if made into gruel, the restorative effect is found still greater, and a smaller quantity of corn then sufficeth. A gradual return to hard food does all for the horse's working condition which can be desired.

Fever is brought on, in some degree, whenever it comes to pass that either of the vital organs may be deranged in its functions. Not unfrequently it happens that a diuretic is all the patient requires, which may be judged of by the state of his pulse after the medicine has operated. When this is the case the feverish symptoms owe their origin to sup-
pression of urine, and the re-absorption of the contents of the bladder into the system. (See "Urinary Organs, diseases of," for 'suppression of urine,) and, after treating the attack simply as such, a cordial ball should then take place of all further treatment, as the immediate falling down of his pulse to a healthy standard will show. Too free use of "pissing balls," however, in the hands of horse-keepers, spoils the action of the kidneys for ever. See book i. page 158. The French give a bottle of their routine wine made warm to stimulate these organs, and most of our farriers administer a quart of ale with the same view. Those are mostly waggon-horses, full of flesh, that so absorb the aqueous particles of the urine, and ultimately the principle thereof (termed urea), and thus light up the fever anew. That derangement in some one or more of the organs of life, which is brought on by cohesion, also affords symptoms of low fever, or of debility, as they then call it, who are at a loss for a specific term. Concerning this cohesion of such organs together, the inquiring reader had best turn to those particles of information on this topic he will find referred to in the Index. Another cause of feverish attacks, generally of the slighter kind, but likely to prove fatal, if neglected, is the retention of his dung, or constipation, which means costiveness; the very first symptoms, in bad cases of this nature is delirium, variously termed staggers, megrim, apoplexy, fits, and which have been mistaken for madness.
COSTIVENESS, OR CONSTIPATION,

May be considered an original disease, and as one producing as well as being produced by fever. That is to say, hardness of the faeces always attends fever, and is frequently the chief cause of it: like the preceding ailment, we have only to remove the cause, and the effect ceases. See also "Diseases of the Liver," and "Staggers."

Causes.—Want of the necessary or usual evacuation by stool, that is sometimes occasioned by the bowels having lost the power of expelling their contents, as described in the second chapter, page 135. Simply speaking, the individual having been long time dosed with purgatives, any neglect hereof causes the dung to harden and obstruct the contractile function of the intestines: heat ensues, and re-absorption takes place, as in cases of retention of urine, until the dung loses all moisture and becomes as hard as baked clay, the lumps that lie in the rectum appearing like so many gingerbread nuts.

The same kind of big fleshy horses as are liable to suppression of urine, are also principal sufferers by constipation or costiveness. Hard food and hard work in warm weather is very productive of this malady, which is often mistaken for inflammation of the bowels; the means of prevention, therefore, are obviously the direct contrary mode of feeding, and also keeping a good watch on the dunging of each horse in the team.

Symptoms.—When constipation attends general
fever, it is then but a corresponding symptom of that disorder, and the reader is referred back a few pages to what is there said on this head. But, when the pulse is not so high as to warrant us in pronouncing it fever, and the dung is ascertained to be hard, there is no difficulty in treating it as simple costiveness. It may be distinguished from colic, and from inflammation of the intestines, by the quiet state of the animal when he tumbles down, which is not the case with either of those disorders; in which pain of the bowels is most evident; whereas, these do not appear to suffer from the costiveness, though the head is much affected by reason of the evil fumes of the stomach ascending there, and ultimately producing delirium and frenzy. Indeed, his actions are those of madness, which the generality of persons attribute to the sick animal. His eyes offer the earliest symptoms by their dullness, contraction, and expansion, succeeded by sleepiness; he refuses his food, he will not work, the mouth becomes hot and dry, the ears cool, and the breathing is difficult or nearly imperceptible, on account of the pressure of the stomach and bowels upon the midriff.—See page 108. The pulsation usually increases, if he be in tolerable good condition; but this increase is ever inconsiderable until fever comes on, and marks the period when blood-letting would be necessary. A dull heavy pulse is more common, until the paroxysms of madness may render this symptom a little sharper and quicker for a short period. At length he tum-
bles down, regardless of the situation, and the action of the head shows how greatly this part is affected, until stupor and death ensue, if the sufferer be not relieved.

**Remedy.**—Purgatives are not always the most eligible medicines even in the earliest stages of the disorder; for, if the constipation has lasted a considerable time, great injury would be done to the intestines by forcing a passage, whereby a commotion might be raised in the stomach, but would act inefficiently where the evil chiefly lies, viz. in the great guts and rectum. As soon as it is ascertained that the animal has not dunged for some days—when he seems uneasy, a fulness is perceptible towards the flank, at the perinaeum, the fundament; &c. and an unusual dryness and tightness is discovered at this latter part, the operation of back-raking should be resorted to. *Castor oil,* one pint, would indeed find a passage in the first stages of the attack, but still good part of the evil usually remains behind; in the more advanced stages, especially when the patient drops, nothing else will relieve him but back-raking. Let the operator strip his arm bare, and having well anointed it with soft soap, lard, or butter (the first being the most eligible), he will bring his fingers to a point, and gently introduce the hand and wrist, when he will feel and draw forth a portion of the indurated faeces he will there meet with, in lumps hard and dry. This he may repeat three or four, or more, times, and leave the animal to himself a little,
whilst a drench is preparing. Trivial as the relief may seem which has been thus afforded to the patient, he will immediately evince proofs of its benefits, by a more sane conduct, by licking forth his tongue, opening the half-shut eyes, by looking about him, and sometimes by getting upon his legs. In this case, plain water-gruel, as warm as a person might take it without inconvenience, may be administered in the quantity of two or three quarts, but if the animal be exhausted, and does not get up without difficulty, or without help, one half the drench may be ale or porter. A clyster of gruel should follow back-raking, in every case. Although he will seem recovered, and may produce a stool, his bowels must next be emptied. In order to this, give a

*Laxative Draught or Drench.*

Castor oil, half a pint.
Aloes, 2 drachms.
Prepared kali, 2 drachms.
Water-gruel, 1 pint.

Repeat the drench next day, leaving out the oil, and doubling the quantity of aloes; or, after an interval, give the usual purgative ball, containing seven or eight drachms of aloes, as prescribed at page 185.

*Inflammatory diseases* of every sort leave behind them a good share of weakness, which full feeding will seldom amend. We must, therefore, restore the tone of the digestive powers by the aid
of medicines, that may be repeated according to circumstances, and the returning strength of the animal.

_Tonic Ball. No. 1._

Jesuits’ bark, 7 drachms.
Prepared kali, 2 drachms.
Ginger, powdered, 1 drachm.
Mucilage sufficient to form the ball for one dose.

In ordinary attacks upon well bred horses, one of these _per day_ for a week will be found to have done as much for the animal as could be desired. But should the coat still appear rough and staring, give the following daily, for a week:

_Tonic Ball. No. 2._

Salt of steel,
Columbo root, and
Bark, of each 3 drachms.
With mucilage to form the ball.

In all cases of subdued inflammation and fever, great precaution is necessary to prevent a relapse, which would render the patient’s case more dangerous than at first; the animal being less capable of bearing up against a fresh attack, by reason of the reductions he has been subjected to. Soft or sodden corn, fine hay, clover, a few vetches, carrots, potatoes, grass cut fresh from a sloping ground, may succeed each other in small quantities, until he may be returned to old corn and hay as usual.
If the heat return at intervals, as usually happens towards nightfall, give

_A Cooling Decoction._

Linseed, 2 quarts.
Coarse sugar, 2 ounces.
Water boiling hot, 6 quarts, poured upon the seed. Let it simmer three or four hours, and pour off the liquid for use when nearly cold. The linseed will bear another water, less in quantity; but some horses will take the seeds also, which may be permitted. Give the whole in the course of the day, at two or three intervals, and repeat the same decoction once or twice more.

_TYPHUS, OR PUTRID FEVER,_

Is _caused_ by long-continued debility, or slow fever, as much as by the injudicious use of medicines administered for the cure thereof. Of these, the most common error consists of cordial medicines, diapente, wines, &c.; which, as they give a short-lived vigour to the animal, are supposed to have done _some good_, and are, therefore, persisted in, until the digestive and secreting parts of the system are spoiled.—See book i. page 74, &c. Typhus is also communicable towards its termination—to man as well as beast; therefore is it but a reasonable precaution to adopt the disinfecting process, as in cases of epidemic, mentioned just below at page 208, and detailed more at large under the article "Glanders," in chap. iii. of this _book._
Symptoms, the same as those in slow fever, mark typhus fever, only the pulse is accelerated upon taking the medicines just alluded to; its irregularity is also greater, until, by continuance of the disease, it ceases to denote any particular state of the body long together. Hence, the supply of new blood carries with it similar effects, the vitals lose their tone, and the muscular part of the system wastes and becomes rotten on the bones; and if the same stimulating treatment has been kept up until the animal dies, his flesh will be found on dissection to have acquired an uncommonly bright purple colour, not only on the surface, but wherever incision is made. Putrescence, in a high degree, has already taken place ere that catastrophe seals the sufferer’s fate! Infection is to be sedulously avoided.

We mention these minor circumstances to prove the real existence of this main type of putrid fever. Another symptom of typhus goes to the same proof, namely, delirium, which follows a continuance of stupidity discoverable in slow fever. A well-marked case was reported in the Annals of Sporting, for Nov. 1824; where it was shewn that the meat was putrid in an extremely offensive degree, and wholly "unfit even to be cast to the dogs."

From the very unaffected and detailed account of the narrator, it appears plain that unskilful persons might be led to apprehend such paroxysms denoted hydrophobia; but a short inquiry into the habits of the horse previous to its last delirium, would go a good way to relieve the anxiety usually instilled into
a neighbourhood by such events. None can say, however, until the experiment be tried, whether animals fed on such meat might not acquire rabies thereby; if our animals of the canis and felis species that are much fed on horse-flesh be not thereby disposed to contract madness.

No remedy can be proposed for such a dreadful malady, better than the knacker's knife or axe.

Mad staggers, as the term is, which has never been satisfactorily accounted for, can be no other than this delirium of the typhus fever, brought on by pushing the animal in his work although labouring under slow fever. None but common or ordinary cart-horses are lost in the staggers; whilst none but a very ordinary owner would so force his cattle to the last extremity during illness. As the above is all we shall find it necessary to say of staggers, we must here remark on the singular impropriety of Mr. Richard Lawrence's considering this as an attack of apoplexy! Since one pang alone denotes the death so to be named.

Rheumatic fever is one of those disorders in the horse upon the existence of which doctors disagree; but doubtless the vicissitudes of heat and cold to which the horse is subjected, whereby the whole system is checked so as to occasion general fever, is equally likely to check the circulation or the muscular action in one or two limbs only. And the pain the animal would thus labour under in the performance of its duties would in time constitute one of the causes assigned higher up for simple fever.
Symptoms.—Stiffness of the whole limb, more frequently of two limbs than of one, or all four, which goes off on exercise and returns in the stable, though this be warm and comfortable. A little relief is afforded by much grooming, friction of any and every sort, promoting the circulation and carrying off the rigidness of the fibrous and vascular system that now prevails, and obstructs the action of the long muscles over each other (See page 90.)

Remedy.—Nothing can be presumed upon as a specific cure, but reason tells us to see to the main evacuation; give a laxative, or a purgative ball divided into three or four doses; but if the kidneys do not send forth urine in the usual quantities, and the dung be not hard, give the laxative-diuretic draught at page 194, or the ball alone at the next page. Should, however, those two evacuations be found in their right trim, going on well, and no cessation to the stiffness, give

Emetic Tartar, half a drachm.
Mix in the corn (damped) twice a day; clothe according to the season, and after two days' sweating, change and discontinue the medicine. Wipe down well, hand-rub the heels, and give the patient walking exercise during the warmest part of the day—for this disorder seldom attacks the horse in summer, when all avoid the sun's rays.

A warm bath was formerly recommended for this disorder and all other aridity of the limbs, which was practised with some portion of success; and a Mr. Foxall, a farrier of repute, though of the old race,
erected a very convenient contrivance for this purpose, in Rope-maker street, Moorfields. We have seen cases, about 1800—1802, of horses which were declared cured by this means, and are now willing to believe it, though at that era a violent family (or trade) opposition existed, so as to prevent our having access to the operation. Almost complete immersion was effected, the rubber and hair cloth was put into complete requisition, and the circulation was thus promoted, by a very different means than the use of the sweating powders; indeed the perspiration thus induced would bear near affinity to that produced by strong exercise. In Germany several such baths were erected, as in Vienna, in Mecklenburg, &c.; but the French invasion annihilated these with other works of art, and we do not hear of new ones being set up in their stead.

Epidemic Fevers, or Distemper.

Cause.—When these appear, from time to time, they may fairly be ascribed to the season; for the kind of attack is not of a nature to become communicative, unless by continuance putridity follows: then, indeed, infection may begin, as would also happen in any of the preceding species of fever. A rainy spring after a mild winter produces an epidemic catarrh, as well as sudden chill, among horses that are out at soil whilst shedding their coats, and the most delicate receive this influence earliest. We may as well consider, that whatever
may give one horse a cold, or affect his lungs, singly applied to him, would, if applied to many, in like manner affect the whole: this constitutes *epidemy*, or the distemper, as we will continue to term it, though a more refined scholar tells us to say 'tis *epizootic*! Cloudy weather and cold easterly night winds, when the weather is warm or murky by day, is more likely to check the action of the lungs or of the whole system, than when a cold season has prepared the animals to withstand the influence thereof. An epidemic prevails sometimes in autumn; but, happen when it may, horses at grass acquire it less often than those which are kept in, upon hard food.

*Symptoms.*—As just intimated, a cold, that harbinger of so many other evils, is what marks the epidemic in every case; in addition to this, the animal will labour under the other symptoms of fever before described, according to its actual state of body at the time of attack. Thus, if the horse be in full flesh and vigour, his veins quickly fill with the stream of life, inflammation of the blood will ensue, or rather, to speak more accurately, of *the vessels* which contain it; hence, *simple fever*, or fever of the whole system follows, as before described, pp. 182—186; but, be he poor, with little blood to receive inflammation, *low fever* is that particular affection which now accompanies the original cold or catarrh.

Hence, we feel no hesitation in classing the epidemic—at least all those which have happened in
our time, with one or the other of those diseases, and recommend treating it accordingly. At its earliest stage, of course, as it assumes the shape of a catarrh or cold, (which in the more malignant cases becomes "Inflammation of the lungs," we should treat it as such; but if not called in until this attack had extended to the animal's whole system, and catarrh had subsided in general inflammation, no reason exists why we should consider it a different disorder, merely because the patients may be more numerous than ordinary! The reader had, therefore, best proceed on to the next head of information, for the details as to the sufferings and cure of a single animal, which we apprehend will instruct him how to treat the many; for, neither the name or the character of the disorder can be changed by this circumstance, however alarming its extent.

If the disorder spreads, and there is good reason for believing it has become infectious, as suggested might happen, at page 206, the disinfecting process hereafter recommended for adoption in case of glanders being brought into a stable, should be employed. See it, at the bottom of the article, "Glanders."

INFLAMMATION OF THE LUNGS.

Causes.—Like all others of its class of disorders, inflammation of the lungs is occasioned by a sudden check being given to the circulation, by cold,
when the animal is heated, either by exercise, food, or close stabling, as before described. How it happens that this organ of animal life is much more frequently deranged than any other, the reader who has well studied the second chapter, pp. 98—105, will be at no loss to account for; adhesion of the pleura, or of the lungs, to the ribs, &c. as described at section 32, being very common: the labour of the horse's action, not to call it pain, is greatly increased thereby, and a certain degree of fever is thus engendered and kept up. The animal is in this manner always predisposed to acquire cold or catarrh; and ultimately inflammation of the lungs comes on, if the cold be neglected. Excessive exposure to the rougher elements, and sudden transitions from this state to a hot and crowded stable, as well as the reverse thereof, added to the changes in our humid atmospheric temperature, accounts for the prevalence of affections of the lungs, in horses of speed especially. Out of the same causes arise several minor evils, to be considered hereafter; as,

Simple cold, or catarrh.
Broken wind, of three kinds.
Roaring.
Chronic cough.

The symptoms of inflamed lungs rapidly follow each other: shivering, difficulty of breathing, loss of appetite and sluggishness, with drooping of the head, become visible in quick succession. In a few hours, if the animal be in good keep, longer,
if out of condition—those symptoms increase, with usually quick action of the flanks, accompanied by hot mouth and short cough. His ears and legs become cold, and he cares not to lie down, or being down, he rises languidly, as if mourning his fate. Sometimes the progress of this monstrous disease is accelerated by his previous habits, if the animal’s constitution be predisposed towards inflammation; but most frequently, nature steps in and affords relief, when—"who would have thought it!"

The cure is sometimes mainly effected by the effusion of watery particles in the chest, which frequently takes place upon bleeding the patient; the practitioner has then little more to do than place himself in the situation of the handmaid of nature, and all will go on well towards perfect restoration. How this effusion is performed, none can know. In this respect, brutes have the advantage of mankind. Suffice it for our purpose, that such is the case, as is shown in the second chapter, where we undertook to investigate the animal functions separately. See sections 19, 20, 21, in particular, at pages 71 to 77. We may ascertain when this effusion has taken place, by an evident remission of the desponding symptoms just set down: the flanks cease to heave so much as hitherto, the animal looks up more cheerfully, he tries to eat a bit, the cough almost ceases, and the warmth of the ears returns, all in a partial degree: but the roughness of his coat, which always accompanies inflammation, does not so soon resume its original suppleness, but puts on
awhile the first symptoms of hide-bound, that goes off slowly. When those favourable symptoms appear, much assiduity in the minor helps to recovery should be kept up, though further bleeding will be evidently unnecessary. It would do positive harm, by debilitating the patient, as the popular phrase goes; or as we should say, weakening him too much.

We have presumed that the patient has been already blooded in this as in all other inflammatory attacks, and that to an amount commensurate to the virulence of the attack, even as much as five or six quarts, if the animal is of full habit. Of this proportionate degree, or quantity, let the reader more precisely inform himself by turning back to what is said on this head and the pulse, under general inflammation, or fever, at pages 172 and 178. The operator will of course follow up the bleeding with the purgative ball prescribed at page 185, in the case of general inflammatory disorders; or, if the patient be a tender one with some breeding in him, rather let the laxative plan be substituted instead of the purgative; to which end, the same ball instead of being given at once, may be divided into three, and given on each of three successive days. In every case of bleeding, a laxative should follow, as before directed, and clysters of water-gruel be administered in aid of both, at intervals of three or four hours. Neglect not tolerably warm clothing; and by good hand-rubbing, beginning [gently, for 'tis sore] at the neck and chest, and so proceeding towards the hind quarters, endeavour to obtain ex-
ternal heat, if not perspiration. When these appear, it is a sign that the desired effusion has taken place, in a greater or less degree, according to the quantity of perspiration. This may be assisted in some degree, after the laxative and clyster have well subsided, by administering a

_Sweating Ball._

Take tartar emetic and asafoetida, of each one drachm.

Liquorice powder and syrup, enough to form the ball for one dose.

Repeat the same in twelve hours, unless much perspiration has supervened in the mean time, when there will be no necessity for repetition. Thin water-gruel will assist the expected perspiration; or, if the animal be a fleshy one, a bran mash may supply its place: either must be given blood-warm, and to a good amount.

The heat of the lungs, which is the immediate cause of the disorder, is visibly reduced by every inspiration of fresh air the animal takes. Naturally, then, this air should be fit for its purpose, or _pure_; at least, not the confined air of an over-filled stable, replete with noxious effluvia and gaseous air: nor, on the other hand, a current of air that issues by doors and windows to the right and to the left, particularly in cold weather, nor even in warmer weather whilst the animal is yet sweating with the diaphoretics just now recommended. As in most
other affairs of life, the best will be found in the medium course; for the noxious stable air having irritated and so predisposed the lungs to receive amiss the blighting influence of the cold air, it follows that either extreme of stimulating, or bracing overmuch, must do harm one way or the other. A full and free inquiry into the best means of employing this main auxiliary in the restoration of health in inflammatory disorders, would be well worth the labour of any veterinarian competent to the task; but at present we will merely observe here, that since it is to this want of ventilation in stables, and crowding many horses together, that we owe all pulmonary complaints and most fevers, the subject is worthy consideration as a preventive as well as a remedy *

Formerly, the general practice was to clothe the animal almost to suffocation, and to close up every aperture by which air might enter the stable; the consequence of which mistaken notion was a severe attack of the lungs, that usually proved fatal wherever these addenda to stable management could be employed in supposed perfection. Not so however, the poor man's or the dealer's horses under inflammation of the lungs, or the more dreaded "epidemic distemper," his stables being more or less pervious, and his horse clothing without the nap, it was no uncommon thing to find these had recovered, whilst the more pampered and more valuable animals fell

* In the Groom's Oracle, this part of our subject underwent long discussion under the heads of "Stable, Air, Gas."
victims to every species of inflammatory diseases. These results were known to many, in various circles, about the time of the establishment of the Veterinary College; and the mutual communications that thence resulted, proved the impolicy of the old plan of adding heat to heat, and increasing the disposition to acquire disease, of the lungs in particular. A revolution which had recently taken place in the human practice regarding the treatment of inflammatory and febrile disorders, also contributed to open the eyes of our veterinary practitioners in this respect, and they (not to appear behind-hand) adopted the direct contrary practice at its greatest extremity: Mr. Coleman advised turning the horse into a loose box, without clothing, leaving open the apertures of the stable, not paying any regard to the seasons. Nought, however, could be more absurd than to suppose that a disease which is produced by cold air should have the continuance of greater cold prescribed for its cure! The rebuke is painful, but necessary.

Our practice has been, to afford the animal as much fresh air to breathe as could possibly be allowed, consistently with keeping out a draught or current; taking care also that none whatever should be directed towards his body, nor any enter the stable from the windward in stormy or cold seasons. With these precautions, in a loose box and well covered up about the chest, but not tightly, he would ever be found turning round to that side where the most air was to be obtained, as if by in-
distinct, knowing whence the readiest natural relief from his sufferings was to be found. In one case, of an aperture being made into an adjoining shed, the patient, a good working horse, was frequently discovered inhaling the little air which was to be drawn thence, though the orifice was no other than a displaced knot of the wood partition.

In general, the disease bends before the remedies prescribed; the hand-rubbing must be continued, particularly of the legs, which in the worst period of the disease are uncommonly fine, but should it last him some time they swell, and in either case prove they are the barometer of the disorder, as well as the necessity of rubbing them. On the other hand, should the pulsation increase after bleeding, and no favourable symptoms appear (as indeed they cannot then be expected), this necessary operation must be repeated to the same amount as at first, or up to a state of tottering, as recommended before, at page 184: this necessity will occur but seldom, and that always with patients in previously high condition. Therefore no danger can be apprehended from this copious discharge; for, at the end of twelve hours, or less, which is the period at which we should a second time resort to the flame, the blood would have returned to its former courses in every respect: the continuance of fever, up to the same original height of the pulse, shows that the particular animal then under treatment, possessed an uncommon quantity of blood, and, therefore, that an unusual quantity should be
taken away in order to alleviate the heat that is destroying it, and will destroy it, if the heat be not subdued, at this second bleeding; for, should this fail, we ought to expect little good from further attempts, though it is desirable to try what we always considered as the forlorn hope—a third bleeding.

Should those remedies fail, suppuration takes place usually in six-and-thirty hours, and the animal is lost. Occasionally, however, it happens with low-priced animals, that the inflammation fixes itself and terminates with the destruction of one lobe only of the lungs, generally that on the right side, the other then performing all the functions; but how perfectly, or for how long time, we have yet no means of ascertaining. At this point of his inquiries, the studious reader had better consult over again, and compare what was said upon the dissection of the lungs, in book i. at pages 98 to 108:

Bleeding, though highly beneficial at first, when the animal system is in full vigour, is extremely dangerous after the inflammation has continued some time. When weakness is indicated by swelling of the legs, or nature seeks to relieve itself by a running at the nose, then bleeding will be harmful; this latter was considered a most favourable indication of crisis in the epidemic fevers of our youth; but let us hope that the groundless fears the rumour of such a plague engenders, never more will visit us with affright: the idea of infection, in such cases, is too ridiculous to admit of refutation, but was nevertheless believed by many.
Weakness follows, of course, every attack of so vital an organ as the lungs, and is a necessary consequence of the great evacuations of each sort his extreme danger has rendered indispensable. But cordial balls, or, indeed, stimulants of any sort, are very improper, and might occasion a partial relapse, if given before the animal is quite recovered. Good grooming, diet, and moderate, well regulated, walking exercise, constitute the means of restoring his strength. Let him be well rubbed down, daily, and his nostrils sponged out clean and often, when the discharge takes place, which most commonly attends the cure; the same offensive matter must be cleansed away from the stall and manger, and he may be led forth daily whilst this business is going on. Hand-rubbing the legs should continue, so as to promote warmth; and they may be subsequently wrapped up, especially if the weather be chilly, with hay-bands, &c. Exercise may be gradually increased as the patient gains strength with appetite. At first, good stout oatmeal gruel, sweetened with coarse sugar or treacle, alternating this with wheat meal, in order to coax his appetite; then oats which have been steeped in boiling water may be given, and next put him to hay of fine odour, in small quantities at a time. If grass or green vetches can be procured, a little, and not too much, may be cut for the now convalescent horse, in order to keep open his body: on the contrary, should he appear low spirited, a little malt occasionally will give him more vigour before leading him out to the field every
day, or leaving him there in clothing whilst the sun may be out, if it shine at all.

Pleurisy, or inflammation of the pleura, where it doubles and divides the two lobes of the lungs (see chap. ii. p. 99.) has been described by Richard Lawrence as a separate disease; but, as the treatment is the same as the preceding, we can see no propriety in making the distinction he does, especially as we cannot know the difference until after death discloses all imperfections. What is more, we could scarcely persuade ourselves that this doubling of the pleura was ever designed to act in the horse; all the full-grown subjects we have examined for years (say 500) having it (the mediastinum) adhering firmly together. Colts ever, and wild horses, not strongly exercised, we apprehend to be exceptions. Of the former several, of the latter one case only has come under our notice; and this a healthy mare that was staked near Simon's Bath, on Exmoor, apparently ten or twelve years old.

Blistering and rowelling are recommended by most veterinarians, as tending to divert inflammatory heat from the more vital part to the surface. The theory is good: in the practice of human medicine we believe blistering is universally adopted; and this is one reason why we ever looked upon rowelling as a means of cure with suspicion, even before we ascertained that the general heat or fever is always increased by the employment of either blister or rowel. Both are of the same nature, but blistering is the mildest, the safest, and equally efficacious; and the practitioner may learn how
either operates on the vascular system by ascertaining the state of the pulse previously to the application, and comparing it with the increased action of that barometer whilst the remedy is taking effect. Subsequently, however, it must be confessed, the agitation of the pulse will subside; and although we seldom find occasion for employing either blister or rowel, yet are we free to allow, that the manner in which inflammation of these organs sometimes terminates (namely in soft tumour), seems to invite an early adoption of artificial means to bring about the same ends. The hand-rubbing just recommended effects this to a certain extent; and if it has been neglected, or lazily performed, then will blistering become necessary to prevent suppuration within.

As this tumour usually makes its appearance and marks the crises of acute attacks, the practitioner may form an estimate of the probable beneficial effects of blistering in any case, by comparing and noting the earliest symptoms of any two cases, in one of which the crisis has been subsequently attended with such a superficial tumour spontaneously, and in the other not so. He will then employ blistering with more reliance on its efficacy than we have found necessary after the hand-rubbing.

When this remedy is adopted for inflammation of the lungs, employ blistering ointment composed of cantharides and sweet oil, or hogs' lard.

**Blistering Ointment.**

Cantharides, powdered, 5 drachms.
Hogs' lard, 4 ounces.
Oil of turpentine, 1 ounce.
Mix, for one extensive application over each side of the chest; which is a neater and more expeditious method of attaining the desired end than seton or rowel. When the latter method is adopted, let the tow used for the rowel be dipped in a mixture of sweet oil and oil of turpentine; and the skin of the breast or belly,—if more than one such seton is employed—be separated only just sufficient to admit the rowel, in order to increase the irritation; but if the surrounding parts swell to an extraordinary size, change the tow for some which has been sodden in digestive ointment.

A COLD or CATARRH.

Causes.—If we sought much nicety of arrangement, the disorder termed "a cold," would have preceded the similar but more malignant attack described under "Inflammation of the Lungs." Both are occasioned by cold applied to the animal's organs of respiration at a time that he is most susceptible of its influence, differing only in the part which may suffer. Thus, when the canal through which the air passes receives the check which is the immediate cause of inflammation, every one agrees in its being merely "a cold," though in most cases no attack is more replete with danger, if neglected.

But the origin and progress of such a check upon the functions of the membrane that lines this canal, having been already fully described in the second chapter, pages 101 and 104, the studious reader must turn back to that part, if he would trace causes
to their effects, and does not presently recollect all that is there said on this topic.

One prolific source of the disorder termed a cold, is found in the shedding of the coat in spring and in autumn, a process of nature always attended with a certain degree of debility or general weakness. Hence it is that the animal sweats profusely upon the least exertion; and, being in this state suffered to stand (harnessed perhaps) in the open air to cool, the sweating is too suddenly stopped, and he gets a cold at least. That the lungs should suffer the soonest of any other organ is not at all astonishing: the very great exertions made by the lungs in the business of progression, is much increased by adhesions and other obstructions to the action of its several parts; and this, added to their exposure externally, and the constant inhalation of fresh, cold, damp air—altogether the prevalence of pulmonary affections in every varied stage ought no longer to be matter of surprise to any person, however casually he may look at the matter.

The horse is subject to cold or catarrh at every season of the year, and some animals retain a cough all the year round, hence termed chronic, other some during their natural lives. But the cold which is contracted in the spring differs materially from that of the autumn. The former attacks the animal when he is full of hard meat and gross feeding—"full of humours," according to a homely but intelligent phrase,—and a malignant sore throat or an inflammation of the lungs is the ultimate
consequence, however slight the cold may have been at first. Sometimes access of all those symptoms we have already described, will be found in the same animal, and he usually bends before the complication of evils and dies, unless speedily relieved by bleeding, &c. From its prevalence at some seasons, we then agree to call it "epidemic," though not a good term, and to recommend a treatment corresponding with the prevailing symptoms, if these be mild, as a simple cold; which form the epidemic fever or distemper always assumes in its earliest stages. On the other hand, the cold or catarrh which the moulting animal acquires in autumn, finds his system reduced by the heat and labour of summer; his blood, in quality or quantity, is scarcely capable of being excited to inflammation, and the first attacks are more easily subdued. Neglect, however, increases the evil at all times, especially with the more valuable well-conditioned animals, some of which are so tenderly managed, that they scarcely can stand the opening of a door or shutter after dark, without catching cold. Neither autumn or winter is the season for remedying this defect in stable management,—if ever it can be got over at all.

Symptoms.—According to the precise part attacked, these vary not only as to appearances, but as to virulence or malignity, always increasing as the complaint descends lower and lower down towards the seat of vitality: the danger being also greatly augmented when the animal is pre-disposed
to acquire *catarrh* in its worst forms by some previous misfortune—as adhesion, &c. *A simple cold* consists in slight inflammation of the membrane which lines the nose, windpipe, &c. the functions of which membrane *in health* are described in the 34th section, chap. ii. together with the manner in which the disease is engendered and conducted downwards. As we find in all other inflammatory disorders, variations in the symptoms occur, according to the previous constitution or evils of the individual, and its actual condition—much more than is attributable to an adverse season, or the immediate cause of disease. For example, if two equal animals be exposed to a chilly night air, that horse which had performed a journey previously to turning out, would catch a cold for certain,—the other most probably would escape; but, if both had performed the same journey, let us suppose, and one of them laboured under the constitutional defect of "adhesion of the pleura," (see page 100,) he would acquire the more malignant cold, known as "inflammation of the lungs,"—his less unhappy mate a simple *cold.*

If the *cold* extend no farther than a check upon the mucous secretion of the membrane that lines the nose, a purulent discharge is first observed in the morning, his eyes become dull and a little bleared; and if the discharge does not run off the cold, in twenty-four hours a short cough denotes that the inflammation is creeping onwards, and has reached the *pharynx*—or chamber of entrance.
to the lungs, described at section 33. The attack upon this point of conjunction between the throat and mouth, will be greatly accelerated by the injury most horses sustain which have been subjected to the brutal operation of being "coughed" by the dealers;—an injury that thus produces latent effects, though the pain were originally little, and that little long ago departed.

We hear this kind of first attack termed "a cold in the head," the second symptom is "a cough," and feel no disposition to quarrel with either term.

In proportion that the attack may be more severe, the symptoms increase, as does the danger. Passing the hand down over the windpipe, at the epiglottis, the animal will shrink if it be sore within, and he will soon evince difficulty of swallowing, and refuse his food: inflammation has begun. When these are not preceded by a discharge from the nose, this symptom does not appear until the inflammation is lowered by bleeding and other remedies: the discharge is then an indication that the inflammation, or heat, has subsided, and no longer demands the adjacent secretions. See page 74, for a more minute description how this demand takes place.

With those symptoms of sore throat others become apparent, and the whole assume a malign tendency proportioned to the severity of the attack and previous state of the suffering animal. As happens in all other inflammatory complaints, the pulse tells of the existence of fever, in its degree;
accompanied by languid eyes, breathing quick and laboriously, and general heat of the skin, without perspiration. In some cases the sore throat is substituted, in some measure, by enlargement of the glands underneath the jowl, which are also attended by soreness, more or less; and, as this species of attack is occasioned by the humidity of a cold spring, or wet autumn, acting upon moulting horses, great numbers feel its influence at once, and gives reason for veterinary writers to consider this general distemper as "the influenza," and an "epidemic."

**Remedy.**—When the sub-maxillary glands swell, as just mentioned, and there is no reason to doubt, according to the corresponding symptoms, that it is the effect of a cold—which may further be ascertained by their heat and tension, let some dis-cutient application be used—as camphorated spirits of wine: but if the inflammation be to a great degree, bran poultice may be applied to advantage. If those enlarged glands already contain matter, the tendency to irritation will thus be reduced; if merely sordid tumours, either application will effect relief, by reducing the size and tenderness of the part, so as the animal may take his medicines with less difficulty. **Steaming** the head for an hour, or applying hot flannels that have been steeped in boiling water, will be found serviceable, taking care to dry-rub the coat immediately after, which also assists to reduce the swelling. If this symptom does not give way before those applications, and
the throat is ascertained to be sore, blistering may be resorted to, taking care to extend it over the whole of the parts affected. See page 218.

As in all other inflammatory diseases, bleeding to an amount proportioned to the violence of the attack, with purgatives and clysters, should accompany the foregoing external applications; and these, with plenty of bran mashes, sodden corn, and the fever powders prescribed at page 190, will reduce the symptoms. Similarly to those also will be the precariousness of his complete recovery, and so should be the care that the relapse, to which he is for a time daily liable, should not reach to a great height. But we need not repeat the general precautions set down at page 201.

Unwilling to leave the reader in a dilemma as to the mode of applying the bran poultice just recommended, and upon the efficacy whereof he should mainly rely, here is the sketch of a bandage proper for such a purpose, with its fastenings.
It will be seen, that unless the remedy proposed is practically applicable, the preparation thereof would be wholly unprofitable; therefore, when a poultice, steaming, or blistering, is deemed necessary, we should endeavour to secure it in the best possible manner; and as most persons are but poor horse milliners, we have undertaken in this instance, as well as in cases of strangles, poll-evil, and vives, to exhibit the best means of retaining the remedies in their proper places.

The cloth to be employed should be of stout but supple linen, as Russia duck, or hempen sail-cloth; or in failure thereof, a fresh sheep-skin, or a piece of Chamois leather might be substituted.

Some recommend steeping the cloth in a solution of gummy substances, to render it water-tight; but such contrivances only add to its unconquerable stiffness, and we should prefer oiled silk, such as is used for umbrellas, if readily procurable, and not too dear for the pockets of those more immediately concerned.

When spread abroad, the cloth will be of an irregular octagon shape, at each corner whereof is to be strongly sewed on a piece of broad tape for the purpose of fastening to the girth, or round the neck, and to a breasting of broad web, which is supported by another piece, that passes over the withers, and which two should be previously fastened together by stitching the cross-piece ends upon the breasting. The two extremes of the bandage will be the fillet across the forehead and the fastening
at the girth; therefore, *measure* should be previously taken of the whole length proper for the individual patient, lest the tie, which would otherwise be necessary at the ears, might discommode the animal, and occasion uneasiness; or, on the other hand, the application would not be kept in its place properly. A single glance, however, at *the cut* will instruct a tolerably expert workman, or *work-woman*, how to manufacture such a bandage as would answer every purpose.

**THE COUGH**

Which accompanies this disorder will frequently remain after the other symptoms have abated; in some cases a *cough* is the only symptom of catarrhal inflammation that the animal suffers under, and in both we should apply ourselves to reduce the inflammation of the wind-pipe, &c. which occasions the cough; for, if not cured *at once*, it baffles all our efforts for a long while, and ultimately becomes what is denominated (from the length of time it has lasted) a *chronic cough*. But no absolute necessity exists for considering these as separate or distinct diseases, the one being but a prolongation or fastening of the other on the system, as described at page 240 below: therefore should our attention to the first attack be unremitting, and the *remedies* applied in turn to each variation of the *symptoms*. If these are accompanied by the *swellings* and *soreness* of the throat and glands, just spoken of, the cough will generally cease, when these symp-
toms are removed; but if not, the cough must be considered as a simple disease, and be treated accordingly. By the way, seeing that after all our care and anxious examination, we can but imperfectly distinguish between some cases of ill-cured catarrh, or the chronic cough, and the incipient cough, or a fresh cold, the practitioner would do well in cases of doubt, when he finds one of those remedies fail to afford the expected relief, to try another, and another—for example:—

When the cough continues, and there is reason to apprehend, from the frequent and violent efforts of the animal to expel the mucous secretion, that this is thick or viscid, and does not come away, though the animal evidently sneezes for that purpose,—the lungs must be relieved by softening the agglutination, otherwise termed "cutting the phlegm." Venesection always effects this end; but, when blood-letting is not rendered necessary by the existence of inflammatory symptoms, as generally happens, the drenches Nos. 1 and 2 will afford relief. As the cough always becomes more and more troublesome as the discharge lessens of itself, or ceases altogether, we may conclude some lurking virus that has fixed upon the lungs is the immediate cause of the cough. In order to enable the lungs to run off this cause by a more copious discharge, give expectorants in the first instance.

*Expectorant Ball.—No. 1.*

Sulphur, $\frac{1}{2}$ an ounce.
Asafoetida, 1 ounce.
Liquorice powder, 1 ounce.
Venice turpentine, 1 ounce.
Mix for four doses, and give one on each of four succeeding nights. See his exercise be moderate, and allow him the cooling regimen before referred to (page 194), as proper for convalescent horses after inflammatory attacks.

**Expectorant Ball.—No. 2.**

Powdered squills, 2 drachms.
Gum ammoniacum, 4 drachms.
Powdered ipecacuanha, 4 drachms.
Opium, 4 drachms.
Ginger and allspice, of each 1 ounce.
Balsam of sulphur, 4 ounces.
Mix, for six balls, with Castile soap, 2 ounces, beaten up with mucilage, treacle, or syrup: to be given once or twice a day.

If this regimen cannot be followed by reason of want of attendants, his bowels at least should be kept in a proper open state by mild laxatives; or, if costiveness prevailed when the cough first came on, simply opening the bowels will then procure ease, if it do not effect a cure. This may be attained by giving, for three or four days,

**The laxative Ball.**

Aloes, 1½ drachms.
Ipecacuanha, 1½ drachms.
Mix with liquorice powder and mucilage for one dose.
These medicines, and every modification of them, which the experienced chemist can suggest, it is desirable should be tried in succession, as the seat of the disorder is so very various and uncertain, that the partial good which one may effect, will frequently be aided by another. To this end the following ball and drenches have been prescribed and used with success—

**Diuretic Ball.**

Yellow resin, 2 ounces.
Turpentine, 4 ounces.
Soap, 3 ounces.
Salad oil, 1 ounce.
Oil of aniseed, $\frac{1}{2}$ an ounce.
Powdered ginger, 2 ounces.

Rub the two last together in a mortar, with a little linseed powder. Melt the first three articles over a slow fire, and then mix in the powders. Divide the mass into eight balls, and give one a day until the patient's water is affected.

**Drench.**—No. 1.

Vinegar, 8 ounces.
Squills, 2 ounces.
Treacle, 6 ounces.

Bruise the squills and pour on the vinegar boiling hot; simmer these near the fire two or three hours, then strain off and add the treacle. Divide into three or four parts, and give a portion two or three times in the course of the day.
CONSUMPTION—WHAT?

Drench.—No. 2.

Bruised garlic, 4 ounces.
Vinegar, 12 ounces.
Pour on the vinegar boiling hot; let it simmer four or five hours, strain off and add six ounces of honey. Divide into three parts or four, and give it in the course of the day at intervals.

But no ultimate cure can be effected unless the diet and regimen is properly followed up; nor, if the animal be pushed in his work whilst the disorder is virulent; and, after all our care, if the cough does not abate, but becomes worse by reason of a new cold, it fixes upon the lungs, and the animal drags out a miserable existence. This has been usually treated of as consumption, by reason of its resemblance to the same disorder in human medicine, from the wasting away, or consumption of the animal system, which accompanies a diseased state of the pulmonary arteries. Of the importance of this part of the system to animal life, to existence and health, the attentive reader cannot fail to be sufficiently aware who has well perused that part of the second chapter of this little manual, in which the functions of the organs of respiration are described with requisite care—pages 98 to 112. The hopelessness of bringing about a cure, after the ruin has proceeded so far as we have just contemplated, must likewise be most apparent to him; we will not, therefore, pursue farther in detail the last wastings of this vitally essential organ of the
animal system, but proceed shortly to notice some other effects of the ill-cured cold or protracted cough.

BROKEN WIND

Is already so minutely described, as to its causes and symptoms, in the second chapter of book i., that we apprehend repetition in this place would prove worse than useless. The reader will, therefore, turn to page 108, and the recapitulation of my treatise on the organs of respiration which immediately follows, at page 110. Generally speaking, broken-wind is brought on by inflammation of the organs of respiration, and acquires a different name, though requiring but little variety of treatment, according to the part which may be the more immediate seat of disease; for it must be clear, that although this may lie in the uppermost part or larynx, in the lowermost part or midriff, or more centrally—the communicable nature of inflammation is such, that the whole must partake in some degree of each and every partial derangement. And this degree will be proportioned to the excitability of the individual's organs of respiration that may be the subject of attack: if the animal contract cold or cough in the vigour of age and health, he will experience its effects in the most frightful shapes; it proceeds to encroach on and obstruct the right functions of the lungs with rapid strides, and if the symptoms do not abate he dies. But, being partially removed, it becomes a chronic dis-
order to the end of his days; and, agreeably to the part which may experience the attack, has it been the practice to denominate chronic cough either roaring—broken wind—thick in the wind—or asthma. Hereupon, however, the doctors disagree.

How this difference arises may be worth a moment’s investigation here, although so large a portion of the second chapter has been already devoted to the subject, and the reader must absolutely turn back to it. At page 109 the thickening of the midriff, in consequence of inflammation attacking the adjacent viscera, was minutely described: this thickening of the membrane also extends to every other part of the lungs, wind-pipe, &c. whenever cold or inflammation prevails; and in the event of its continuance, the thickening of the membrane remains long after the virulence of the disorder may be subdued. If this state of the organs of respiration extend over them generally, the patient may very justly be said to be “broken winded;” when this extends to the thickening of the pleura only, he would then be thick winded, or short in the wind, as he would also in case of adhesions of the midriff, as described at page 109, already referred to. Neither affection, however, can fairly be set down for broken wind; though both those membranes being affected might properly enough be considered “a broken manner of drawing in and expelling the wind,” for the inspirations and expirations are in this case extremely irregular, broken, or variable; whereas, when the air-cells are really
broken, or burst into each other through great exertion, then the air escapes with difficulty, and the expirations are now slower than the inspirations (as before said), and both together constitute irregular respiration, or true broken wind.

But of controversies there is no end. James White and Richard Lawrence were for some years at issue on these points; White having taken up Lawrence rather sharply, and somewhat unjustly, if he meant to impute error to the latter, as regards the symptom of respiration just spoken of, for each writer was right in his separate position: as they disagree as to what constitutes broken wind, so they could not of course agree as to the symptoms. See pages 159, 160, of White's first volume. This author also disorders his own positions at the same place, in two other instances, which we should not have noticed but for his tart rebuke of Lawrence for attributing the term broken wind to the thickening of the membranes. In this view of the case, it will be seen, we cannot agree with that very clear-headed veterinarian to the full extent; but we do not, therefore, harshly refute a gentleman and scholar for not agreeing with us upon a simple term of science.

White says, page 160, "The lungs of broken-winded horses that I have examined have generally been unusually large, with numerous air-bladders on the surface." Yet, in the next page, he opens a broken-winded subject, and says, "The lungs were lighter (meaning less) than usual, and without
the air-bladders, contrary to the state Mr. Lawrence describes." What Lawrence had said was this: "The most common appearance of the lungs in *broken-winded* horses is a general thickening of their substance, by which their elasticity is in a great measure destroyed, and their *weight* (*i.e.* size) specifically increased. On this account air is received into the lungs with difficulty, but its expulsion is not so difficult. Thus, in *broken-winded* horses, inspiration is very slow, expiration sudden and rapid, as may be seen by the flanks returning with a jerk." (P. 123, octavo edition.) And he is correct as to these two motions accompanying the thickened membrane or substance of the lungs; only we should have termed the disorder *thick wind*, and not *broken wind*, when all would have coincided with White's statement, barring his own self-contradiction as to the *size* of the lungs, which Lawrence had mistaken for *weight*, and which had met with the counter assertion of being "specifically *lighter*." On this point of their dispute, however, neither the one nor the other could possibly *know* aught with requisite certainty; and we, for our part, are inclined to believe, that the lungs of *high-bred horses* are specifically lighter than those of the cart breed, saving that the whole organs of respiration are much less muscular in the first kind than in those of the latter, the skirt or border of the midriff in particular. On the other hand, the hearts of blood horses invariably run of a larger size than those of the common English horse.
Vide proof at page 115. One cause of broken wind, or rather that mainly predisposes the animal to contract this disorder, is voracious feeding, which distends the stomach inordinately, and for a while gives to the animal a short-lived vigour and healthy appearance. This induces its proprietor to put him upon his mettle, to try the extent of his powers at progression; and as he will best perform those feats upon a plentiful feed, the action of the midriff and lungs thereby becomes laboured, and the proper expansion of the lungs is impeded. Heat and tension are the immediate consequence, and broken wind of one or the other species is the remote consequence. Horses that eat their litter, and other hard substances, are similarly predisposed to broken wind; namely, by the great distension of the stomach, and inability of inspiring a sufficient quantity of air to fill the lungs, whence the inert cells, or portion not distended, fill up, contract, and become useless, or, upon sudden action and over-distension, they burst at once.

Cure there is none for broken wind, and therefore all that can be done by way of alleviating its symptoms must be effected by management, or, as it is more generally termed, by

Regimen. Of course, the groom would avoid exposing the animal to fresh cold, and not push him too hard on a full stomach; nor indeed, give away a chance of increasing the malady by the same means as we have just said originally brought it on. He will, on the contrary, follow an oppo-
site course of treatment, and as much as possible regulate his feeding and exercise upon moderate principles, for the stomach and bowels are always affected by broken wind. Hence it is, that flatulency accompanies broken wind of every kind, so that the animal, in his endeavours to cough, usually breaks wind after an effort or two. Much medicine is not requisite, and, in slight cases, far from desirable; tonics, bracing air, and regular hard meat feeding, broken or sodden, and given in small quantities, will do more for the horse than physic of any sort. For the first, Peruvian bark, or cascarilla in small doses, may be given occasionally, adapting the quantity to the bulk of the animal.

Tonic Ball.

Cascarilla, Gentian root, \{ 1 to 2 drachms of each, Oil of Carraways, 10 drops; with Mucilage enough to form the ball. If irritation of the bowels is indicated by a certain protrusion of the anus, add of opium 10 to 12 grains, and give the sedative clyster. When the cough is particularly troublesome, or the animal seems to labour much in respiration, give occasionally the following

Ball.

Dried squills, powdered, 1 drachm, Gum ammoniacum, 3 drachms, Opium, 2 drachms, Ginger, 2 drachms;
With mucilage sufficient to form two balls; and give one on each of two successive days, but repeat not too often, as the opium is liable to harden the feces; give salt in his corn, 2 ounces daily.

If there is reason to apprehend the horse swallows his corn without grinding it, as commonly happens, bruised or sodden oats should be given, after the bowels have been discharged by purgatives, should alteratives not be deemed equal to the urgency of the case. Those prescribed at pages 242, 244, are applicable in this case also; inasmuch as the two disorders bear very near resemblance to each other in this respect. Give green food, succulent roots, and bran-mashes, as there recommended. Let the water be soft, not too cold, and given in small quantities at a time, and frequently.

As broken wind produces disordered bowels, and is reproduced by it, the connexion or sympathy between the two, thus plainly demonstrated, should be employed in the alleviation of the former in all its stages, when it has been of long standing. The means of attaining this object have been shown; and when the value of the animal under treatment is equal to the care and expense, it frequently recovers so much of his former powers of free respiration, that his cure will seem for a short time fully effected, and if so, up to a certain quantity of work, and to a certain speed; but extend either too far, and the disease is irremediably fixed. These appearances, however, are completely illusive; upon the least extra work he relapses into his former dif-
difficulties of continuing it, and the *cough*, the *roaring*, wheezing or labouring of the flanks and chest, return as bad as ever. If the work be very hard, as always happens when the horse has been sold deceptiously, and the new master would try its utmost powers, the relapse is then worse than before; he hereupon becomes a confirmed roarer, by the wind and lymph being driven inside the membrane that lines the wind-pipe, and causes titillation of the very fine blood-vessels that traverse it. Hence the number of lawsuits that are instituted to recover the valuable consideration paid for broken-winded horses that are returned upon the hands of the sellers as *roarers*, that never were known to either groom or stable-boy for roarers, before the day of action or trial. Hence, too, let us charitably suppose, the contradictory evidence often given, and the flat, downright cross-swearong that usually takes place on such occasions. For the horse having been partially *made up* for the purpose of sale, *i. e.* nursed, patched up, and to all appearance "right in all his parts," the fact of his *going* in pain comes out by way of his skin at first, and the new purchaser being generally desirous of trying all he can do, the ruin is effected, by pushing him too much, of driving the wind inside the membrane, as before described.

*Hereditary roarers.* Early in the present century, a question arose among breeders, whether the gift or the curse of roaring descended from parents to their progeny. The decision was looked
for with unusual anxiety among the breeders of farm-horses in Norfolk and Suffolk, where a famous horse, well-built in every other respect, was much sought after, even subsequently to his being denounced a *roarer* prepense. Would his stock take after him? was a problem very desirable to be set at rest, when Mr. Wilson, of Bildestone, late Sir T. C. Bunbury's, propounded the question to Mr. Cline, an eminent surgeon and anatomist in London. In reply, Mr. Cline says, "The disorder in a horse which constituted a roarer, was caused by a membranous projection in a part of the wind-pipe, and was a consequence of that part having been inflamed from a cold *, and injudiciously treated. A roarer was not, therefore, a diseased horse, for his lungs and every other part might be perfectly sound, but when a horse was in strong action, his breathing became proportionally quickened, and the air; in passing rapidly through the wind-pipe, was in some degree interrupted in its course, and thus the roaring noise was produced. The existence of this in a stallion could not be of any consequence. It could not be propagated any more than a broken bone, or any other accident †." Unfortunately, * Not always so, Mr. Cline. The wind being driven underneath the membrane that lines the throat, obstructs the free passage of the wind; lymph is often secreted in the receptacle thus formed, which hardens in time, and is only capable of relief, by opening the windpipe. † Our human anatomist is very nearly right as to an accident not being descendable; but seeing that roaring did descend to the first generation, we must infer that this was "an accident of birth," and not a contracted one, which might possibly go on farther.
however, for this opinion, and not exactly in accordance with our own, several of that horse's get turned out roarers, and thus set the matter at rest.

**CHRONIC COUGH**

Is already defined to be the remains of an ill-cured cold, which may or may not have been a cough originally. It bears close analogy to simple broken wind that is seated in the wind-pipe or its branches, of which it may be considered a continuation, or the natural consequence of neglect, with more inveteracy. How this effect would so accrue was described at page 233—237; and the analogy is still further corroborated by the fact, that the treatment for cough of long continuance is precisely that which is found serviceable for broken wind, the situation of the two disorders making the only difference in either respect. Again, the symptoms of both may, by long and careful treatment, be so reduced as to seem cured, for a longer or shorter period, and both will return in the shape of roaring, upon the animal being put to sudden hard work, as mentioned in the last pages. The corresponding symptoms of both are also so nearly alike, that we merely comply with custom while recapitulating these for the use of readers who might not choose to consider that horse broken-winded, which to all appearance is only affected with "an old cold in the wind-pipe." But, let the first term appear to an owner ever so formidable in sound, the latter is
no less dangerous in effect, and both are alike liable to terminate in roaring.

The symptoms which denote chronic cough are nevertheless so slight, that it is too often considered as but a small remains of the more alarming catarrh, which its owner vainly imagines will go off in time, as the other disagreeable symptoms have done. In this hope he is invariably disappointed, if the means of reducing it be deferred. After the more violent symptoms of catarrh have subsided, and the cure may reasonably be considered as complete, the horse returns to his usual desire for food, and, as in the former case, soon eats voraciously; he is, moreover, denied water oftener than twice a day, perhaps not so much, so that, when at length he does get a drink, he gulphs it up as if famished. This is commonly the cause, and the first indication of the cough which follows immediately after, but is often mistakenly attributed to his improving too fast after his long illness; and it is considered only fair that "he should be allowed to recover himself completely." Precaution is thus lulled in fancied security, and unless relief be afforded before the damp season of autumn returns, this symptom increases to obstinate confirmation; until time renders cure hopeless, alleviation or abatement of the coughing being all that lies within the power of medicine or stable management to effect for it—the aid of the former being then of little avail. Very few small proprietors of horses use timely precautions in this respect, and the disorder goes
on: large owners having more experience, adopt early measures, and if pursued with proper vigour, these usually prevail in lowering the symptoms.

An occasional cough is also brought on by high feeding, which, as it arises from the rapid production of fresh blood, is termed plethoric cough, by way of distinction. Of this symptom it would be needless to tell the better informed, perhaps, that we have but to take away the cause, and the effect ceases as matter of course. This, however, does not always follow; for the cough sometimes remains after the gross feeding has been reduced in quantity and quality. In this case, it must be considered as chronic cough, and treated as such, by emptying the bowels, &c. as above directed.

Remedy. As in the case of broken wind of every other kind, the horse eats every substance he can come near, chronic cough being sometimes produced by over feeding, as well as always producing that symptom. Therefore, when a horse has cough, occasionally, for two or three days, his appetite being good, we had best conclude he is too full, and must be emptied by an alterative or purgative, according to the emergency of the case: if he be of gross habit, or has failed in the proper evacuations; if his heels swell of a morning, or his coat stares like hide-bound, the cough will vanish before the following

Purgative Ball.

Barbados aloes, 7 drachms,
CHAP. I.] Remedies for Bad Habit. 245

Castile soap, 3 drachms,
Ginger, 1 drachm;
with mucilage sufficient to form the ball.

Failing to stale properly, the patient's heels will swell, in addition to the cough, and both may be got rid of by a diuretic ball or two at farthest. If the evacuation by the skin be at fault, through cold or otherwise, accompanied by cough, the perspiration will be restored, and cough depart, by the exhibition of emetic tartar, two grains, every day twice in his corn, until its effects are perceptible on the skin, and the cough then diminishes. This, however, is a very slow remedy, though sure, and is sometimes given in much larger quantities, to the amount of a drachm and a half. The preparation is very simple when given in the form of a ball, being made up of liquorice powder and mucilage only, of a sufficient consistence to retain that form. If much heat of body is perceptible, though the pulse may not indicate inflammatory disorder, add to the foregoing ball, nitre, 4 drachms.

But, whatever course is pursued, if symptoms of a bad habit of body are discoverable, it will be advisable to administer the foregoing purgative ball once or twice previous to adopting any other means of cure. If those symptoms of a bad habit of body do not appear, then the purgative should be of a milder nature, and given at the same interval.

Mild Purgative.
Aloes, 4 or 5 drachms,
PERIODICAL COUGH, AT GRASS; [BOOK II.

Castile soap, 3 drachms,
Calomel, 1 drachm,
Ginger, 2 drachms,
Oil of carraways, 10 drops;
mucilage enough to form the ball for one dose.

Some horses are more delicate than others, and being then irritable about the throat and chest, are liable to contract a periodical cough, which becomes chronic without due care. Such animals should be exposed as little as possible to any violent weather, or sudden change of the temperature: they are also the kind of animals that benefit greatly, or suffer the most, by a summer run at grass, according to the heat, the dampness, or dryness of the season, and the precautions used previously to, and at the turning out. Neither should such tender animals, under circumstances of chronic cough, which generally affects their coats also, about the chest in particular, be treated with a purgative, even of the mildest form, but with alteratives instead.

**Alterative Balls.**

Aloes \[\frac{7}{12}\] 12 drachms each,
Hard soap, \(\frac{1}{3}\) drachm,
Emetic tartar, \(\frac{1}{2}\) drachm,
Ginger, \(\frac{1}{2}\) oz.

Oil of carraways, 1 drachm;

with mucilage enough to form the balls into six doses. Give one every morning until a loose stool is produced, which may happen on the third or
fourth morning, or longer, as the animal may be more or less relaxed.

Even with this moderate employment of laxative medicine, the kind of animal for which it is most desirable will be very unfit to turn out to grass of a sudden: as, on account of its delicacy, it will in that case be more likely to acquire a small hectic cough, which no one attends to, because of its triviality, until time renders it chronic, with all its attendant consequences. Roaring and broken wind, are among these evils, and have already received as much attention here as they separately require.

Frequently it happens that a horse has a constitutional cough, or one which comes on upon high feeding only. Again, a disposition to plethora will produce the same kind of cough, but either seems only an effort of nature to disburthen itself of something offensive. In this case, the rapid repletion of blood drives it into the smaller vessels that line the pipe, &c., and there cause the titillation which after two or three efforts ends in cough, and so on repeatedly. None but those which are in some slight degree or other already afflicted with chronic cough are ever so attacked, it is apprehended; indeed we have frequently remarked how excellent a test of "bad in the wind" was good feed, or a large feed, with work upon it. In this case, the administering of attenuants will thin the blood, and give immediate relief.
Attenuating Drench.

Nitre, \( \frac{1}{2} \) of each half an ounce.
Yellow resin, \( \frac{1}{2} \) of each half an ounce.
Oil of aniseed, 20 drops.

The oil should be first well mixed with the resin, and the whole given in a quart of water-gruel. Much stronger preparations of the same materials are commonly given, but the nitre disorders the stomach when given to the amount of an ounce per day; which being done with a view to aid the secretion of water, the same end may be better attained by adding to the above drench—Camphor 1 drachm. Recurrence of the like affection may be prevented in some measure by giving the same prescription in another form, which is in general reckoned more convenient—namely, as a cough powder, substituting aniseeds, 1 ounce, for the oil, and pounding the whole together: mix with the corn, at twice.

DISEASES OF THE STOMACH AND INTESTINES—INFLAMMATION.

Whenever one of those organs is affected, with inflammation particularly, the other soon feels the effects of the attack. This arises from the proximity of the two, or the continuity of the digestive faculty, which is mostly carried on in the intestines,
as the reader of tolerable recollection well knows was so described in Book I. page 131—5. Corrosive poisons, we there said, carry on their work of destruction upon the internal or villous coat of the stomach until the ruin is complete; but, although horrid inflammation accompanies its ravages, we would not class such a species of accident under any other head than "Poison:" to call it by its symptom would be delusive. Neither is the inflammation caused by worms, proper to be taken into consideration here, though in this case both organs are affected at the same time; but the bottleneck question involves other considerations, besides the best means of destroying them, of preventing the access of this irritating insect, or of alleviating the effects of its bite and adhesion to the villous coat, alike of stomach and intestinal canal.

With those exceptions, there is no greater difference in the causes, symptoms, or means of cure of inflammation in the stomach and intestines, than exists between those of the great and the small gut. Inflammatory pain in the smaller parts of the alimentary canal will ever be more acute than those which attack the larger ones; thus, when the stomach is the seat of disorder, the pains will be duller, the paroxysms less distinctly marked, and the pulse but little altered; but, when by continuance it reaches the small gut at the lower orifice of the stomach, then will the pain and anxiety of the animal increase greatly, and the symptoms thereof, visible in his manner, will become more distinct,
rapid, and vehement. The pulse increases in number, in sharpness of vibration, and irregularity. Such is the difference also that is discernible between attacks upon the colon or great gut, and on the smaller guts. But all this refers to the first attack; for after a while, if the means adopted are insufficient to check its career, the ruin goes on to affect the whole abdomen, and the animal dies of gangrene in excruciating torments.

*Causes.*—Much the same as those which occasion acute fever in all ordinary cases; that is to say, a sudden check given by cold to the action of the parts, while these may be in a state of great excitement, through over action, hard work, excessive heat of the weather, the operation of cordials, &c. By this latter means stallions are sometimes destroyed prematurely, even without catching any cold, or this part of the system receiving any check whatever: in these cases, excitement has been carried to the utmost pitch by high feeding, and stimulating the male, until nature gives way, or rather, I might say, catches fire almost, and if not speedily arrested, the heat soon destroys the functions of all the abdominal organs of life.

To stage horses, inflammatory complaints usually prove fatal, from the same immediate cause; the animal being fed high, and pressed forward to the accomplishment of his daily task, regardless of the first indications of this disease; and in summer time, we witness numbers of such dropping down in harness, sometimes whilst going along, seldom
giving warning of approaching dissolution. But, whatever be the previous state of the animal's bodily health, he can rarely stand the mistreatment he receives from his driver—whether post-boy or coachman; *viz.* that of being driven through ponds and large rivulets, while he is yet perspiring greatly through fatigue and the heat of the weather. Almost every posting town offers some such ready watering place, and few drivers can resist the pleasure of thus abridging the labour which the heels of his horses and the wheels of his coach require at his hands. Long rests in currents of air, or unsaddling horses under similar circumstances, are alike productive of inflammation of those or some other part of the animal's inside, if it do not bring on fever of the whole system—as before observed, page 172. The kidneys or the liver are sometimes alone affected by this species of culpable neglect; but in either case, as the effects are not immediately perceptible, the disorder creeps upward unheeded, or seizes the animal violently, so that it dies at the next going out, of *Apoplexy*.

Neglect of the necessary evacuations, or the discontinuance of those which have been customary, even though injudicious, will occasion an accumulation of dung in the great guts when they are least capable of bearing it; upon this, pressing the horse in his work will bring on inflammation, as it will sometimes after a *heavy feed* and *water*, which some injudiciously give on account of a hard day's work lying before him. The same happens to
horses that are inordinately fat, when hard worked; the dung that is then eliminated bears with it a portion of the slime or mucus that lines the intestines, and this appearance has obtained for this species of inflammation the term molten grease, of which we come shortly to treat.

Adhesion of the gut sometimes takes place, so as to cause partial obstruction to the passage of the aliment; at others, tubercles are formed on the mesentery, that holds the bowels in position; and in either case the secret is disclosed by a staring coat, which some mistake for the worms. Both those affections are the effect rather than the first cause of inflammation of the part, and may be distinguished from "the worms" by the state of the pulse, by the heat, tension, and soreness evinced by the patient on passing the hand over the belly. See page 140, Book I. The reader will also perceive, upon turning back to pages 74—76, in what manner this adhesion is effected, viz. by the exhaustion of the moisture that is designed by nature to lubricate the parts.

Colic of long continuance, if the animal is worked while this is on him, is another prolific source of inflammation of the intestines; as is the drinking cold water copiously, while in a state of perspiration, or after a trying journey, which is always attended with spasmodic colic of the stomach and bowels at first, and of inflammation sooner or later, according to the temperature of the individual. The necessity of getting rid of the lesser attack before it acquires
a permanent and dangerous aspect must be obvious; and as the treatment proper for either is at total variance with the other, the one requiring warmth and stimulation, the other a cooling and *reducing treatment*, our first duty is to ascertain precisely the exact nature of the attack; for a mistake on this point would, and *does frequently*, prove fatal—aye, in human as well as in horse medicine. Therefore it is, that we have judged it expedient to set down here in the form of a table the symptoms that will enable the practitioner to distinguish between the two kinds of attack.

**SYMPTOMS.**

A table for distinguishing between the Colic or Gripes, and Inflammation of the Bowels, by the symptoms that mark the character of each.

<table>
<thead>
<tr>
<th>Spasmodic or Flatulent Colic</th>
<th>Inflammation of the Bowels</th>
</tr>
</thead>
<tbody>
<tr>
<td>1. Pulse natural, though sometimes a little lower.</td>
<td>1. Pulse very quick and small.</td>
</tr>
<tr>
<td>2. The horse lies down, and rolls upon his back.</td>
<td>2. He lies down and suddenly rises up again, <em>seldom</em> rolling upon his back.</td>
</tr>
<tr>
<td>3. The legs and <em>ears</em> generally warm.</td>
<td>3. Legs and <em>ears</em> generally cold.</td>
</tr>
<tr>
<td>4. Attacks suddenly, is never preceded, and seldom accompanied by any symptoms of fever.</td>
<td>4. In general, attacks gradually, is commonly preceded, and always accompanied by symptoms of fever.</td>
</tr>
<tr>
<td>5. There are frequently short intermissions.</td>
<td>5. No intermissions can be observed.</td>
</tr>
</tbody>
</table>

Whilst marking these distinctions, which ought to be kept in mind while prescribing for disorders
so nearly alike at first view, but differing so widely
in effect, the reader is earnestly requested to turn
to the Index, and there find the page at which we
have thought proper to treat pretty much at large
of "Inflammation of the Kidneys," "Diseases of
the Urinary Organs," &c. He will there perceive
how fatally these affections have been mistaken for
"Colic;" he will learn that this unhappy error is
likely to happen more frequently than would at the
first glance be imagined; and he will observe that
the symptoms correspond in many respects with
those in the second column above—therefore re-
quire an equally correspondent course of treatment,
but that the deposite of stone in the kidney is an
incurable disorder, that admits of no remedy.
Furthermore, the reader will observe, that the
whole of the article alluded to, on "Calculus, or
Stone," requires his strict attention; and also bear
in mind what is there said as to calculous sub-
stances which are deposited in the cæcum or blind
gut, producing symptoms so much like spasmodic
colic, that much care is necessary in applying the
appropriate remedy in each case, lest he precipitate
the patient's catastrophe.

Of these symptoms the state of the pulse is the
surest indication of the approach of an inflamma-
tory attack of the bowels, or any other viscus; and
the particular part which is then suffering must be
gathered from other circumstances. If he has long
suffered colic without relief, doubtless inflammation
has taken place, and gangrene is likely to follow:
this is the harbinger of death. *Cohesion* of the gut together sometimes baffles the best treatment for colic, and soon devolves into *inflammation*. In either case, the remedies proper for colic must be abandoned, and others more adapted to the change of circumstances be employed instead.

Whenever the cause of inflammation of the bowels may fairly be ascribed to the quantity or quality of their contents—without adding to the irritation by any extraordinary exertion, its approach will be very slow, and denoted by sluggishness and the refusal of food at first. As they are mostly working cattle that are thus attacked, the evacuations are not sufficiently minded, or the attendant neglects to make mention how these have discontinued in a great degree, or changed their appearance—the dung being then hard, and the urine high coloured; hereupon the pulse increases, and the outrageous symptoms described in the second column of the *table of symptoms* go on to a frightful extent, endangering the lives of bystanders. Even in this stage, the progress of the disease may be arrested by prompt and vigorous measures, adapted to the kind of animal that may be the subject of attack, and the circumstances under which the present alarming symptoms may have been brought on. If a heavy lumbering waggon-horse, that owes his disease to alimentary indulgence, we shall find no higher operation necessary than emptying the overcharged canal by *force of arms*, i.e. back-raking; but the high-couraged stage-coach horse, which
falls under the exercise of the lash, and the influence of a vertical sun, has seldom aught within him of that kind to part with, and requires the introduction of some substance or liquid that shall cherish the afflicted stomach and bowels, and alleviate the burning heat that, ascending to the head, causes his delirium. Presence of mind, however, or the adroitness which much practice teaches, is frequently wanting for the first-mentioned remedy; and the means of applying the second is so seldom at hand, that the animals are too often left to their fate and are lost. But we anticipate the remedies.

Remedy.—From the rapid progress made by this disorder, when left to itself, and its usually disastrous termination, the duty of attending to the pulse of his animals as before insisted upon (at pages 180, 199), will strike every intelligent horse-proprietor, as the very best means of guarding against the fatal consequences of inflammatory attacks. He will by this means be apprised of the earliest approach of the disease, and thus enable himself to meet it in its mildest form: he will compare this certain indication of heat—whether fever of the whole system, or inflammation of a particular part, with the state of the patient's urine, which will then be high coloured, and the dunging defective. The rectum will be dry, hard, and hot; the belly on passing the hand over it towards the sheath will have the same feel; the animal will shrink from the touch, his eyes appear languid, or partly shut; as the disorder proceeds they assume
unusual redness, or what has been termed blood-shot. The mouth is hot.

Up to this stage of the disorder, the first remedy will be clystering and bleeding the animal freely, if he be not very aged, or of spare habit; immediately after giving the following

*Laxative Drench.*

Powdered aloes, 2 drachms,
Subcarbonate of potass, 2 drachms,
Water-gruel, 1 pint,
Castor oil, half a pint. Mix.

If delay is to be apprehended in procuring the above drench, give castor oil one pint, or in default hereof, salad oil two pints, whilst the drench is preparing.

In ordinary cases, a voluntary stool will be produced at or soon after bleeding, occasioned by relaxation of the tenesmus that constitutes the disease. If the dung comes forth in small quantity and small hard knobs, like gingerbread nuts, the straight-gut must be cleared by the hand, according to the directions given at a preceding page, 199. And, when the constipation has endured for a long time, the hardened dung will not come away at all without this manual operation of back-raking, which must be performed the more assiduously as the difficulty may be greater and the dung harder. Let a warm clyster be thrown up that is copious enough to fill the emptied gut, at the least.
**Clyster.**

Water-gruel, from 4 to 6 quarts,  
Epsom salts, 4 or 5 ounces.  
Inject warm, with a large syringe, or ox-bladder and long pipe: perform this operation effectually.  

A second and third should follow, a little warmer than the first, and after an evacuation has taken place, the next clyster may be made without salt, and a small degree thicker than at first. Its effect will be to remain and nourish the parts nearly in the same manner as a poultice does an external inflamed wound.

Too often, however, those early indications are entirely neglected; the animal is harnessed in to his day's work, and the consequences are both dreadful and dangerous to behold. If he be a stage-coach horse, or destined to take his *turn* at a posting-house, his sluggishness and refusal of food is usually attributed to "a little overwork;" and the much abused *cordial* is commonly administered; which brightens him up for the renewal of his daily task, and accelerates his fate, unless rescued as by a miracle that is very seldom wrought. In these cases, the first symptom perceptible to the driver is the horse's leaning against its next horse; but, upon being *touched up*, it makes fresh exertions according to its quantity of courage, until it falls down with closed eyes in excruciating torments, lashes out behind, and beats about on the ground,
seldom having the strength to get upon its legs again. Bundles of straw should be placed for the afflicted animal to roll upon, and his head pressed down with the hand whilst the severest paroxysms expend their forces. When at length he gets up—which may be considered a favourable sign, that proves his strength is not wholly subdued—he may be supported into a stable. Mean time, however, an examination of the rectum must take place, and the manual operation of emptying it be employed—if need be; that is to say if hardened dung should be accumulated there. At any rate, water-dung in large quantities must be prepared, as well for administering by way of clyster as of drench; in both, giving it now without the addition of salt, and in the latter manner nearly cold. By these means the alarming symptoms will diminish greatly; but if there is still reason to apprehend that obstruction may prevail in the larger intestines, this must be got rid of by means of the oily laxative prescribed at page 257, and the repetition of clysters in quantities, and administered with a vigour sufficient, to reach the evil.

Bleeding, of course, would be adopted, to the amount of four, five, or six quarts, according to the exigency of the case and the size of the animal. If the blood become buffed, as it is called by some, or sissy on the surface, a second blood-letting is necessary to complete the cure. Low, but nourishing diet, should follow; as bran-mashes, stiff gruel, and afterwards sodden corn; the return to hay pro-
vender being made gradually, and then of good quality.

In very bad cases, the return to full health and vigour will be slow, and a relapse is to be dreaded, as a fresh attack would prove much more obstinate than the first. The dung, by its quantity, consistency, regularity, and general appearance, will afford the best means of judging when the bowels are completely cleared of their offensive contents; for it not unfrequently happens that several tolerable stools may be procured by the help of medicine, and yet some lumps, replete with danger, remain behind. The pulse, that great criterion of health or disease, by dint of low living, may have regained its natural state, and so remain steadily for a tolerably long period: but watching the dung for a day or two will corroborate that main indication of health, or by its irregularity dispel an ill-founded reliance on the completeness of the cure. Yet will the administering of purgatives, or even alteratives, of aloes in particular, be found full of danger, as tending to irritate the bowels anew. The same may be said of all stimulants whatever, whether applied externally or given in the form of cordials, notwithstanding the animal may evince signs of returning pain, and these be ascertained by the corresponding symptoms of low pulse, warm legs and ears, to arise from spasmodic or flatulent colic only. For these returning pains are usually occasioned by the soft kind of regimen just recommended, to which the patient may have been subjected during this ill-
ness for the first time since it was a foal. We have known a small feed of corn or two effect relief from lowness, in the case of horses which had been long time previously used to hard food: if these be devoured voraciously, this will tend to prove 1st, that the change is desirable, and 2dly, that the next feed should consist of broken corn—or a new disease will be engendered. Adopt the tonic system, recommended generally, at page 201.

MOLTEN GREASE

Is but a variety of inflammation of the intestines when the subject of attack happens to be very fat, and little accustomed to exercise; when marked by costiveness, it may be treated as such; or, if attended by a looseness, may rather be considered as a spasmodic effort of nature to relieve itself of an unnatural load. The vulgar name given to this affection of the intestines is farther supported by the popular notion that the fat, or grease, which the individual possessed in a superlative degree, had melted (or was molten) and passed into the guts, whence it was expelled with the fæces. This, however, is physiologically impossible, notwithstanding the support such a notion has received from some revered authors; the appearance of slimy unctuous matter along with the dung, more particularly when this is much hardened, being no other than the mucous secretion described at pages 74, 75, as designed by nature to defend the surface of the intestines from the injurious action of hard
substances that might be taken into the stomach. Indeed, this intention of nature in providing such a defence is demonstrable in the fact, that the harder the knobs of dung may be that the animal presseth forth, the greater is the quantity of this greasy, unctuous, or mucous secretion that is eliminated along with it, and which gives name to the disorder. Probably, the secretion of this *grease* may then proceed with more celerity; its access may be greater, the more it is thus required by nature to defend the alimentary passage. This supposition is drawn from the fact just stated; but, whether the well-founded conjecture be too hastily hazarded, is for the more minute inquirer to conclude upon, or investigate farther, as may seem good to him.

At any rate, the doctrine of *effusion*, or the passing of those secretions, whether mucous or æqueous, from one part of the system to another, as nature or accident may require the supply, is tolerably evident from another circumstance that is often recurring in cases of *molten grease*. [The subject is more fully treated of at the page just referred to.] The perspiration of the two secretions in succession, here referred to, is pretty well recognised, and is easily proveable, in the manner there set down; the unctuous, mucous, or greasy secretion (call it which we like) of the *external surfaces* following that of the more liquid, æqueous, or watery kind, after any great exertion. Horses that contract *molten grease* are ever those which have been highly fed, without exercise sufficient to excite visible per-
piration thereby: and the feverish heat of the body occasioned by high living and indolence, in time exhausts the whole supply of the æquous secretion. So much is this the case, that the animal's discharge of urine becomes less and less as its seclusion is continued, until the decided access of fever takes place, and we notice its colour is higher and higher as its quantity decreases. [Look again at section 55, page 156.] As before explained, the secretion of mucous matter takes place within the guts, &c., or that surface which is next to the food; on the other side, and every other part of the animal system, the watery secretion destined to lubricate the parts, to keep them supple and to prevent adhesion, takes place. On that side (which is popularly considered the outer surface!) good quantities of fat accrue, all along the whole length of the intestines, which is usually scraped from slain beasts, and preserved as tallow. From this source is derived that access of grease, which, as I have said, is greatest as the inflammatory symptoms may be higher. When this has long been the case, and stools are at length procured, a long thin wormlike portion of this fat comes away with the dung; which would be of itself a sufficiently alarming appearance, though wanting animation, but for the well-known, but inexplicable doctrine of effusion, or communication through the gut: this appearance, then, of a long tenacious fatty portion of thin membrane, which usually accompanies molten grease, should be considered
as little more than denoting the crisis of the disorder.

Let the system be reduced according as the state of the pulse may dictate—for which consult again page 171, as to bleeding, and page 197, as to treating him for "costiveness" simply. If heat and irritation be perceivable to the touch and sight about the anus, without high pulse, the first symptom may be reduced by administering

**The sedative Clyster.**

Camphor, 4 drachms,
Spirits of wine, 3 or 4 drops,
to promote solution, and add
Sweet oil, 2 ounces.
Mix well, and then add thin warm water-gruel, 2 or 3 quarts.

As before intimated, molten grease is rather an effect than a cause of disease, and partakes of colic in one of its forms and of inflammation in the other; the symptoms that enable us to distinguish when the one or the other prevails being precisely those set down at page 253. Allowing somewhat for the feverish symptoms that always prevail with such fat and bloated animals as are subject to this disorder, the practitioner cannot commit himself to the guidance of a better test than that just referred to, nor more safely adopt a treatment that is more likely to reinstate his patient in health, for very little danger attends molten grease, in either form. For the treatment which is proper in cases of spasmodic colic
affecting fat animals, the reader is referred to the next head of information.

THE COLIC, GRIPES, OR FRET.

This disorder has been frequently referred to, under the preceding head of Inflammation of the Intestines, to which it bears great affinity in some of its points—as already stated; the cause of both being nearly the same in most cases, and long continued colic always ending in inflammation, if not effectually checked in time. Much of the difference that exists between the two kinds of attack depends on the previous state of the animal attacked: if it be a high-fed and hard-worked animal, whose digestive organs receive a sudden check, he contracts inflammation in the first instance; but one that is lower kept, and therefore not so irritable in any part of its system, is soon troubled with spasmodic affection of the intestines, which receives the name of gripes, or fret in different counties, as it does that of flatulent colic in most of the books that treat of animal medicine. Colic, however, is the general name given by most stable people to every pain of the inside (of man and horse) that occasions writhing, or other demonstrations of that pain, which few can discriminate in their own persons, much less in their horses. To this undiscriminating manner of naming disorders that require such very different treatment at our hands, is to be attributed the loss of many lives annually. In this anomalous manner of treating those disorders
it is painful to notice one of the most scientific veterinary writers of our time has fallen. We do not find in Mr. Richard Lawrence's "Complete Farrier" any reference whatever to inflammation of the intestines; though under the head of "Colic, or Gripes," he proceeds to describe the symptoms of inflammation in such a manner as might mislead ignorant or half-taught persons to treat both alike, and thus destroy their horses.

A violent cold; or a slight one, will also determine the disorder one way or the other, when the individual's system may be of no decisive character at the time of contracting it. That a low state of the animal system is favourable to engendering spasms of the intestines, is inferred from the circumstance, that subsequently to a horse afflicted with inflammation undergoing the copious evacuations recommended in the preceding pages for the cure of that disorder, he is frequently visited with spasmodic affections that require sedatives and tonics to restore the patient to complete health.

Causes.—Next to drinking cold water, and catching cold by exposure to air or water whilst heated, the eating of bad, ill-got, or rank hay, is a prolific source of spasmodic colic. If it lie in the intestines chilly and comfortless, and thus predispose the animal to acquire cold, the cause of epidemicical colic is plainly attributable to such bad hay, for it then prevails usually over certain districts, and mostly among country cattle. Pushing a horse in his work when large lumps of undigested matters
distend parts of the gut, will bring on spasm, torpor, and inflammation in succession. Horses that gormandise much, being worked hard, and the stomach becoming empty, occasions the fret, and inordinate action of the guts expulseth the mucous secretion that is designed for their defence. This constitutes molten grease, of which we have treated largely just above, and we are decidedly of opinion that the expulsion of offensive matters in all cases where the animal evinceth but small sensations of pain, is but an effort of nature to relieve itself, and ought rather to be assisted than abated by hot or "cordial medicines."

Strong astringent purgatives, oft repeated, or neglect during the operation, are frequently succeeded by flatulent colic, that soon becomes inflammatory if the internal commotion be not judiciously arrested by sedatives. Cordial balls and drenches, as they impart a short-lived vigour, so when their stimulating effects die away, they leave behind a debility that is more excessive as those factitious effects have been most intense; in this respect, the cause and its consequences assimilate closely with those which succeed the disease of inflammation, and the debility which follows the cure thereof, with spasmodic colic. Diapente, and other provocatives, that are given to stallions in the season, leave behind them the same species of debilitating effects after covering, and would devolve into colic first, and inflammation afterwards, but that those horses' evacuations are well looked after, and
the system of stimulants is kept up by repetition. This treatment, however, cannot always succeed; so we frequently find that stallions die suddenly of inflammation in the intestines, in the spermatic cords, or other parts of generation. Cases of death, in actus coitu, from the same causes, are upon record. We mentioned this before, at page 62.

All horses, indeed, that have been pampered in the above manner, or by being kept in close stables, or having their water chilled, when they come to be subjected to common usage, are most likely to suffer by colic in its worst forms. Horses that are made up for sale by dealers and cunning breeders, in order to give their coats a sleek appearance, upon passing into the hands of new owners, commonly undergo attacks, more or less acute, of spasmodic colic, if they do not at once fall ill of inflammation of bowels, kidneys, or bladder. With animals so circumstanced, mere flatulency or looseness may be considered a favourable termination of the making up system before alluded to.

Symptoms.—These, as contradistinguished from those which denote inflammation of the intestines, will be found in the table of comparative symptoms at page 253. In addition thereto, other symptoms, that mark the degree of spasmodic attack, require equal discrimination; seeing that the treatment which may be highly proper in the more virulent attacks, would be injurious if employed upon every slight occasion. Neither is it every horse which shows signs of pain in the inside that hath the colic, even
though the symptoms set down in the second column of the "table," at page 253, do not appear; for, he may be afflicted with pain in the kidneys, or inflammation of the bladder, which the attendant should ascertain before giving the stimulants that may be very proper in most stages of colic, but would accelerate the disease incident to those "urinary organs." The careful reader should therefore turn to the subjects "Kidneys," and "Urinary organs," before he proceeds to treat the animal simply for colic pains.

In its mildest state, flatulent colic first appears in the form of violent purging, which is in fact no positive disease, as before observed, but an effort of nature to rid itself of a collection of offensive matter, either indigestible, cold, or irritating. Of what precise kind this may be at any time is ascertainable upon the view, and requires only to be assisted in coming off, provided but little pain is evinced by the animal. If he be a crib-biter, pieces of extraneous matter are usually found among the dung, as bits of wall, of wood, litter, &c.; if an aged horse, or one that has been kept on bad hay, his food comes off undigested; if a very fat horse, the mucous secretion comes away as described under "molten grease," just above—and all these require at most some of the milder purgatives that are least likely to irritate the bowels.

Whenever the ears become cold, after gripes have continued some hours, it is a certain indication that inflammation has taken place of some one
or more organs, mostly of the intestines. This is sometimes discovered, when too late, to attend a rupture of the distended bowels through the peritoneum (vide Book I. page 140), when the protruded gut mortifies (as is found after death) in consequence of strangulation. After this, the pain seems to subside, and the animal dies quietly. The ruin that has taken place is only told on dissection. Yet do most ignorant persons pronounce horses still alive to have a "twist in the-guts;" and stranger still, they prescribe a remedy for it, although it is incurable! The ears act also as a good barometer, when inflammation of the kidneys may be apprehended, or inflammation of the neck of the bladder is more than suspected, on account of the difficulty evinced by the patient in passing its urine. If the water come off high coloured, it is a sure sign of inflammation, which is further corroborated by cold ears; if of its natural colour, the ears will be warm, and the difficulty in staling is occasioned by the hard distended gut pressing upon the ureters and neck of the bladder: procuring a good stool or two, or a clyster, then restores the functions of those organs.

The earliest symptoms observable in his manner, is when the horse looks round at his flanks occasionally, whisking his tail at intervals; he looks at the attendant, if there be any breed in him, seeming to implore help. He stamps with his hind feet alternately on the ground, sometimes striking at his belly. As the pain increases, these symptoms are oftener repeated, and with more vehemence: he
gathers his legs under him, as if preparing to lie down; which he at length effects, rolling about in the stall, and getting up again repeatedly. It may here be remarked, that this rolling on the back is well calculated for affording temporary ease to the great gut; but should inflammation have already attacked these, or at the kidneys, this rolling on his back would but increase the pain of the animal; and his jumping up instantly upon his legs, as if the spur or whip had been applied, goes to prove the existence of inflammation at one or the other viscus, as those symptoms vary.

Cure.—Too much care cannot be exercised in ascertaining the precise nature and amount of the disease; for, in error in this respect resides extreme danger of life, which is too often sacrificed to precipitancy, to ignorance, and presumption. As soon as a horse is pronounced "ill of the colic," the attendants, without investigation, proceed to give "something to do him good;" which is ever some of the stimulating class of domestic remedies. Warm ale, with ginger, peppermint water, gin and water, and Daffey's Elixir, are the common popular remedies usually applied in this case; and, provided the disorder be really flatulent colic, relief from the pain must follow the exhibition of either one or the other. Frequently, however, it happens, that the doing good is carried too far, and inflammation is thus superinduced, if it do not already prevail. By such persons, every internal pain is pronounced "the colic;" and they all
conclude that what has removed it once will remove it again, without being certain that it is the same disorder—as they do, that whatever is good in small quantities must needs be more so in larger ones. But we have already observed, that the removal of umbilical affections, whether flatulent or inflammatory, by rough, harsh, or protracted means, scarcely ever fails to produce the other concomitant disease, and the inflammatory symptoms no sooner subside, than the jaded vessels contract spasmodic affections, as do also the continuance of flatulency, and some of the means of curing it, superinduce inflammatory symptoms.

In whatever shape the horse is attacked with these disorders, the first and most obvious duty is the employment of clysters, to be repeated at short intervals, with this single variation; viz. in cases of relaxation, where the animal is already purged, the clyster to consist of simple water-gruel only; but when the patient's bowels are overloaded with hardened dung, the addition of salts, as prescribed at page 258, will be found most effectual. In the absence of Epsom salts (for no time must be lost), a handful of common culinary salt may be employed, in the quantity of four or five ounces. Back-raking, too, should be assiduously applied, when the body is in this state, as recommended in the case of inflammation, at p. 257, with the laxative drench prescribed at the same page, or the simple salad oil, or castor oil in default thereof.

In ordinary cases, when the attack is not of the
most violent kind of either description of colic, that is to say, when neither purging nor constipation prevail extremely, let the following be given.

No. 1.—Colic Drench.

Epsom salts, 4 or 5 ounces,
Castile soap, sliced, 2 ounces.
Dissolve these in a pint of warm ale, and add
Oil of juniper, 2 drachms,
Venice turpentine, 2 ounces.
Mix well together, and give it warm; repeating the same in four or five hours, and if the symptoms do not visibly abate, repeat once more. Tincture of opium is sometimes substituted for the turpentine to the amount of 4 drachms; but the drench is thereby rendered exceedingly nauseous, and should be given deliberately. Opium is, moreover, least proper when a tendency to costiveness is discovered to exist.

No. 2.—Colic Drench.

Tincture of opium, 2 drachms,
Oil of juniper, 2 drachms,
Spirit of nitrous ether, 1 ounce,
Tincture of benzoin, 4 drachms,
Aromatic spirit of ammonia, 3 drachms.
Mix together, and preserve the same in a bottle, and give in a pint of warm peppermint water. Repeat in three or four hours.

When the case is not very alarming, a neater
manner of giving opium, in the form of a ball, is recommended:

_Sedative Balls._

Asafoetida, 4 drachms,
Opium, 4 drachms.

Make into four balls with liquorice powder and syrup, and give one every two hours. The balls may be given along with the oily laxative at page 257; immediately preceding it, or before the laxative has operated. These balls are very serviceable to travellers on their journeys, and may be given to horses that are liable to contract spasmodic colic, which is the case with heavy, fleshy, draught cattle, with post-horses and the like.

Colic is never fatal, unless it terminate in inflammation; whilst it should be kept in mind, that colic always ends in inflammation if not removed in time. A day, or at most two, may pass away without danger and without relief, in ordinary attacks of spasmodic colic; and where a looseness takes place, a short time longer of neglectful carelessness might not terminate the life of the animal; but, when inflammation commences, a shaking or undulation of the tail is observable, with evident shivering of the whole frame. The danger is then great; especially when each fit of shivering is not succeeded by perspiration: mark that.

If the costiveness is not well removed when those symptoms, with cold ears and legs, come on, let the belly be fomented with warm water by
means of woollen cloths steeped therein. A horse rug may be used to advantage in this way by two men, one standing on each side the horse and fomenting the belly by bringing it nearly together across the back, and supplying it with warm water. After half an hour's application, or more, let the coat be well rubbed with dry cloths, and the animal wrapped in body clothing. The clystering, and other remedies recommended in cases of inflammation, should then be employed with assiduity. Lastly, employ the tonic system recommended, generally, in all inflammatory cases, at page 200.

DISEASES OF THE LIVER.

1. INFLAMMATION.

2. THE YELLOWS, OR JAUNDICE.

When we consider the vast active functions the liver has to perform, in cleansing the blood which takes its passage through it, and the secretion of bile, that becomes more obnoxious as this organ is more diseased, we ought to feel surprise that so large an animal as the horse has so few ailments springing out of that source, rather than lament the frequent existence of this one. For, the two names set down at the head of this article, agreeable to the general practice, have only one origin, viz. inflammation; but differing as to the amount of heat, and situation of the evil, which is scarcely distinguishable until after death. The symptoms of both are the same, and the first attack ever becomes the
most lasting, if the remedies be delayed, or wholly neglected.

Having been led to enter somewhat at large into the causes and remedies for certain affections of the liver, while describing its structure and functions in the first book, pages 146 to 152 we shall find less occasion to add much more at this place. The reader will of course turn to that page.

**Cause of inflamed liver.**—Great heat of the whole circulation, (vide page 173); also, inflammation of the proximate organs, as of the diaphragm, to which the upper portion of the liver is strongly attached, as well as of the kidneys, to which the off-side thin portion of the liver is adjacent, communicate their baleful heat to this fine organ, and an increased formation of bile is the immediate consequence. The blood, in passing through the liver, leaves behind, or else acquires a portion of this extra heat, which reproduces more at its next passage through it, more at the next, and so on, until the inflammation of the whole liver is completely effected. *Increase* of the bile or gall proceeds in the same ratio, until the gall duct, that communicates with the small gut, is closed by the uncommon heat of the inflammation, or by the thickening of the gall, or by both operations united, no matter whether. At any rate, the bile which ought to be conveyed away by stool, is returned into the system, and occasions yellow skin—whence the vulgar name. When this occurs, we apprehend the inflammation lessens, but the communica-
tion with the bowels does not always return to a healthy state, though we believe it to be partially the case. Indeed, constipation in the first instance often obstructs the passage of bile into the bowels, and thus increases the evil. Overfeeding has the same effect, and both produce light temporary yellowness, which goes off upon the removal of the cause, generally followed by diarrhoea. The feverish symptoms also which accompany the commencement, also pass off leaving a low, irregular pulse, until the bowels resume their wonted course, either naturally, or by the aid of medicine.

Symptoms of inflammation before yellowness comes on.—As this last and surest indication of diseased liver only appears when the evil is a confirmed one, and is extremely difficult of cure, particularly in old animals, we should assiduously set about ascertaining its commencement, so that the remedy may be promptly employed, and a further procrastinated mischief be timely prevented. And the more so, seeing that what constitutes a remedy in its earliest stages is no longer so after a long while has been spent in delay.

Whenever inflammation, or extraordinary action of the kidneys, or of the diaphragm, has lasted some time, in ever so small a degree, in that degree will heat or inflammation attend the liver. It enlarges upon the accession of this heat, visibly so when this has continued a while, but may be previously ascertained by the feel. As will be seen *

* In the plate of skeleton, at the parallel lines H, 28, 29, is placed
the liver extends much farther back than the last rib, and a little beyond the false one. Here, a considerable protuberance appears when the liver is enlarged, and disease may be ascertained that is attended by the presence of pain only. Old horses, which have been well bred, retain chronic affections of the liver to a very great age; and this is frequently the main disease under which they suffer for several of the last years of their lives: many such animals die without liver, for want of sufficient action, or being of so small a size, that nought but its situation could assure us it ever had any functions to perform. Horses so visited with a trifling undetected affection of the liver lose their courage, and gradually sink into lethargy: we often hear such animals accused of being “used up, done for, or, 'tis all up with him,” and yet driven about to the last moment of a painful existence.

When the attack is rapid, with painful inflammation, arising from the causes just set down (page 276), the pulse is the sure indication of the ruin that is going on, by its irregularity, quickness, and uncertain vibration. See page 179. One lobe

the kidney of the near side; whilst the off-side kidney in the same subject would be intersected by the lines 27, 28. With this latter, the right lobe of the liver lies in contact, and when an enlargement of it takes place, it may here be seen and felt; so that, when the access of inflammation and tension render it painful only, the doctor should press the points of his fingers (of the left hand) gently behind the last or false rib several times, whereby he will ascertain whether any and what degree of pain the patient endures. If seated high up on the liver, the horse will not, of course, flinch at the first slight touch.
only suffers in this case, and then the animal turns its head round dolefully to that side, from time to time. Constipation always accompanies the more acute inflammation of the liver.

Remedy.—That species of inflammation, which comes on with dangerous strides, when the subject of attack is of vigorous habits, must be met by a bleeding proportioned to the state of the pulse, and that without delay. For, it communicates its baleful feeling to the intestines, and either death ensues, or, being suffered to expend its virulence, as will happen by voluntary diarrhoea, provided the animal possesses strength sufficient, the bleeding will then be wholly unnecessary; or being persisted in after purging comes on, will confirm the slighter affection just spoken of probably to the end of his days. A purgative ball should accompany the bleeding, as in all other cases is prescribed generally at page 184; but, if the animal produce a stool voluntarily, it will be seen that the disorder has taken a natural turn, and neither the operation nor the physic is required.

After bleeding, let the sides be rubbed with the blistering ointment (vide page 219), or apply a rowel to the chest. This latter, however, is a doubtfully eligible remedy, though always employed by the regular collegians. The patient will require the same treatment, as to diet and regimen, as for inflammation of the organs of respiration and general fever, before treated of at page 178, &c.; in the course of which his pulse and faeces should be
watched, and a relapse provided against. *Calomel* is that medicament which more immediately acts upon the liver, and *unless the horse scours*, as just observed, should be administered in the form of

**No. 1.**—*Alterative Balls.*

Aloes, 9 drachms,
Calomel, 1 drachm,
Hard soap, half an ounce.

Mix with mucilage sufficient, and divide into three balls: to be given on three successive nights, unless a thin stool comes off with the second ball. But in case of a *scouring* coming on, give the

**No. 2.**—*Diuretic Alterative.*

Oil of turpentine,\[\text{each 1 ounce.}\]
Hard soap,\[\text{of each 1 ounce.}\]
Ginger, powdered,

Mix with flour and mucilage to form three balls; and give one on each of three successive nights.

**THE JAUNDICE, OR YELLOWS.**

*Cause.*—Inflammation of the liver, or any other obstruction of this organ, which, preventing the escape of the bile into the *duodænum*, or smallest gut, through the gall duct, by reason of this *duct* being inflamed, or choked up with the thickened bile, whereby it is again taken up into circulation, and thus pervades the whole system. When the *inflammation* is very great, the disorder quickly carries off the patient; the inference therefore is,
that poor animals alone acquire the yellowness which gives name to this disorder; though it must be allowed that the same effect may be produced by over-feeding and constipation, by swallowing hard substances, or otherwise offending the said gut, or the pylorus orifice of the stomach, as described at pages 134, 137. The situation of this lower orifice may also be seen depicted in the plate of a skeleton at the intersection of K 26. At that page we did not choose to speak of negatives, and, therefore, omitted to notice the fact, that the bile or gall secreted in the liver of this animal proceeds at once, as soon as it is formed, into the gut, without being detained in a sac, or gall bladder, as is the case with all other animals, except deer; so that, upon any revulsion or hindrance to its free entry to the bowels, the gall must necessarily return to the numerous cavities that pervade the whole liver, and its reabsorption by the blood is no longer problematical.

**Symptoms.**—A dusky yellowness of the eyes, bars of the mouth, and tongue. The dung scanty and pale, generally hard, and covered with slime; but in some few cases the horse scours; that is, when slight inflammation of the bowels also attacks an ill-conditioned horse. The pulse is that of low fever, and the same kind of drooping inactivity, with loss of appetite, noticed under that head at page 191; differing from it only in respect to the seat of disorder, the low fever being general, or of the whole system, jaundice of the circulation only.
Sometimes, however, yellowness comes on without the other symptoms, after an inflammatory fever; an occurrence that cannot fail to be foreknown. Genuine jaundice may further be discriminated by the yellow lips, yellow saliva, and dark urine. From the latter appearance we may draw these curious inferences—viz. that the colouring of the bile which has ceased to impart its property to the dung, having gone with the blood to the kidneys, there leaves its darkest or more earthy particles—the lighter or brighter ascending to the heart, and passing through the vascular system there imparts its yellowness. By this providency of nature we see how it is that malevolent particles in the blood are cleansed at the kidneys, and pass off by urine. Thus it is that grease and other tumours are cured by judiciously stimulating the kidneys. The urine voided, as above described, which is ever done with evident pain and difficulty, leaves on the ground an appearance of blood.

Cure.—Young horses and fat ones are easily cured: they have indulged too freely in good living, on hard meat, and require no more treatment than a good physicking. Give the usual purgative ball (page 185), or the alternative ball, No. 1, prescribed in page 280. After the bowels have become settled, give bran mashes, green food, and succulents, according to the season. Bleeding is seldom necessary, or proper, which the state of the pulse will show.

The Liver is also frequently affected with tu-
mours on its fine surface, as well as with ulcers or schirrus, which are all the effects of an evil state of the blood, of over action, and probably of accidents from external injuries, communicated by the kidneys.

We can easily conceive that the thin parts of this large viscus may be diseased, and even inflamed, without causing derangement of the biliary function, further than increasing its action, and by thinning the blood over much, it obtains more bile. The animal then waxeth thin, though devouring his food as usual for a while; and we may ascertain when this evil has begun by the state of his dung, principally as to colour, which will then be of a much deeper hue. As pale dung is a symptom of suppressed bile, so is deep colour an indication of a superabundance, that is caused by over action, which is itself occasioned by the heat of the liver, from some cause or other. One of these causes may be "inflammation of the kidneys;" or, it may be occasioned by ulcer; and we set about ascertaining which, according to the instructions set down at page 185. In the latter case give the alternative balls, the same as for inflamed liver, at page 280, according to the circumstances there discriminated; but it never happens that a scouring is of a dark colour, and a strong purgative would not be required in this case, though the bowels should be kept moderately open. When there is reason to apprehend that the adhesion of the ulcer to the intestines has taken place, as described at page 149,
the animal should not be worked hard, though moderate exercise is desirable, and so is
Change of physic, as in all cases that require alteratives. When the coat is *staring*, the following balls should take place of the preceding,

*Alterative Balls.*

Emetic tartar, 3 drachms,
Aloes, 9 drachms,
Hard soap, 1 ounce,
Ginger one scruple.
Mix, and divide into three balls; one to be given on successive nights, unless two have operated.

**INFLAMMATION OF THE KIDNEYS.**

This being one of those diseases which bears resemblance to another, and as the mistaking and treating the one for the other generally proves fatal, reference should be had to what is said under the head "inflammation of the neck of the bladder." Such a mistake of the disorder in the present instance is very likely to be made by the common observer, inasmuch as the kidneys, as soon as they become inflamed, secrete *much more urine* than in a state of health, and any one noticing this, and subsequently its defalcation, as the disease goes on, may easily imagine the bladder itself is affected, or its *neck*. It is worthy of remark, that mares are more subject to affections of the kidneys than horses, particularly brood mares; while, on the contrary,
they are less liable than the male to inflammation of the *neck of the bladder*, in consequence of the shortness of the vagina: its straightness, too, affords easy proof of the *real seat of the disorder*;—that essential prelude to effecting any cure whatever. See page 158.

**Causes.**—Too constant use of the diuretic powders and balls, (the "pissing balls" of the shops,) commonly bring on inflammation of the kidneys, by the irritation and over-action of these glands which is thereby occasioned. When one kidney only is affected, though in a mild degree, if suffered to continue, it communicates to the other in process of time, but sometimes proceeds with such rapid strides as to affect the intestines, when mortification and death ensues; but we have no means of ascertaining when this last incurable mischief has taken place, until after the animal is dead—nor could the knowledge thereof be made available for any present purpose, though finely instructive as to future cases: then it is the kidneys present an enlarged and rotten appearance and feel, their texture yielding to the slightest impression of the finger nails, which shows in what degree and how long they have been affected.

A hard blow across the loins will injure the kidney on the side so struck, and soon affect the other also. Sudden transition from an open airy situation to a stable that is close and hot, violent riding or driving, or an ill-cured affection of the bowels, whether inflammatory or spasmodic, will affect the
kidneys in more or less degree. Those causes all together combine to affect these parts more frequently than is generally supposed, the reason for which misconception is nevertheless most apparent to us: it is owing to the neglect of all the milder symptoms; some persons imagine that unless bloody urine be produced, the defective staling is caused by something less remote than the kidneys, though in all obstructions of the liver, as we have seen above (page 281), the quantity of blood these send to the kidneys leaves some of its colouring property to the water. This class of unreflecting people generally fix upon the bladder as the seat of disorders that so affect the quantity of water. They almost invariably give stimulating medicines, that do but increase the disorder, and confirm the ruin it is their duty to prevent.

Symptoms.—The most evident of these has been just now alluded to, and was formerly treated as a distinct disease, under the coarse title of "Bloody Urine:" it is, however, considered as happening more frequently to horned cattle (as "Red Water") than horses, and to the female rather than the male.

When this symptom appears, it is accompanied by a corresponding symptom, viz. great tension and soreness of the part; which may be ascertained by passing your hand along the back, over the kidneys, [at F, 27—29, in Plate 1.] whereupon the animal will shrink from the touch. No doubt can then exist that this bloody urine indicates genuine inflammation of the kidneys; and of course that we should
treat it as such, and nothing else—nor by any other name. If the pain and tension cannot thus be ascertained, then "bloody urine" is caused by obstruction in the liver. Another symptom that may be relied upon is a stiffness of the hind leg on that side which may be attacked first; afterwards, when both kidneys are affected, the animal becomes stiff of both legs. This symptom does not occur in "inflammation of the bladder," (i.e. its neck), and is a good distinctive mark to go by, when we may be labouring under doubt as to some other point of resemblance between the two diseases. In all stages of this disorder, the horse stands as if he wanted to stale; straddling, and making the most exertion when he voids the least urine (then always bloody), which shows the destructive tendency of these efforts on the gland itself. The consequences are, that the kidneys waste away, and the disease communicates to the bladder, until the final ruin—mortification ensues. The practitioner, in this case, will not fail to look at what is said respecting "stone and other calculi," a few pages farther onward. In all cases of constipation, turbid urine prevails, and that obstruction being removed this symptom abates of course. See Constipation page 183.

"Suppression of urine" is also a sure indication of the genuine inflammation of the kidneys; that is to say, the capacity of secreting it is nearly extinct, or it is performed with exceeding great difficulty, pain, and danger. Whereas, in affections of the bladder, the secretory function is not lost by
the kidneys (or suppressed); but, when the urine has been sent into the bladder, this latter has not the power to expel its contents. How this happens, see above, at page 158, &c.

But the most prolific source of diseased affections of the kidneys, and the least perceptible of any, are ill-cured pains of the intestines and of the liver. These leave behind them certain morbid effects that are not immediately felt nor easily discoverable, but nevertheless work their ruin imperceptibly; for, as previously observed, when the kidneys lose their function of secreting urine, they enlarge, and after death scarcely bear the pressure of a finger point without breaking.

Cure for inflammation of the kidneys.—Seeing that strong diuretics are reckoned with truth, among the causes of diseased kidneys, no man in his senses would think of administering any such, after he has ascertained that this organ is disordered in any way whatever. Such, however, is too often the practice of unskilful persons, who, after noticing the defective quantity of urine produced, think of restoring the animal's capacity for producing more by medicines that stimulate the parts, which already labour under a disease of too much stimulation. "As in all other cases of inflammation or fever [how often have we not repeated the same words!] when the pulse is high, let the animal be bled according to the amount of the attack." See general observations at the head of this chapter, pages 171 to 181. Give warm clysters frequently as there pre-
scribed; and with a similar view give him a loose stall, if the paroxysms are so acute as to cause him to lie down and get up again repeatedly. Immediately after bleeding, give castor oil 18 ounces, provided the animal has not dunged during the last twenty-four hours, as commonly happens; less may suffice in general; but a horse that has been much addicted to diuretics, though hisbowels may be in a tolerable state, will not suffer aught from a small portion of aloes immediately afterwards:

Mild Purgative Ball.
Aloes, 4 drachms,
Castile soap, 4 drachms,
Emetic tartar, 2 drachms.

Mix, with mucilage enough for one ball.

Should the symptoms abate nothing in consequence of this treatment, in a few days, the bleeding must be repeated and the purgative too. Rub over his loins a stimulant

Embrocation.

Spirits of wine, 2 ounces,
Soap, 2 ounces,
Camphor, 1 ounce.

Mix, and apply it with the palm of the hand to the loins; cover the animal up well, and be careful how it is subsequently exposed to the air. The mustard embrocation is equally efficacious: being rubbed on soft sheep-skin, cover the loins there-with. Give the cooling decoction in large quanti-
ties, as at page 202; and if the animal is disposed to eat the sodden seeds, it may be permitted to indulge: they are little nutritious, however, when the saccharine has been drawn out by the hot water.

The food should consist of bran mashes, green food, and the cooling regimen already recommended in all cases of inflammation, at pages 178, 202, to which the reader is earnestly referred for some general directions as to his rule and conduct, equally applicable in all such cases.

DISEASES OF THE BLADDER.

These are really much fewer than are commonly ascribed to it, the bladder being but the vehicle or outlet for several evils that take their rise higher up; and among these we have already denounced the alarming appearance of "bloody urine" as a disorder of the kidneys and liver, page 286. Neither is the "suppression of urine," nor its converse "diabetes," justly ascribable to the bladder, but to the kidneys; for, if these secrete none or imperfectly, little or none can be sent into or escape out of the bladder; but "retention of urine" may be a fault of the bladder, or rather a collapsion of its neck; and the means of procuring its escape was before recommended at page 158, &c.

Inflammation of the bladder, (its neck) and consequent "incontinence of urine," are the same disorder; the latter, being the irritating effects of the
inflammation only, we shall consider this separately, referring those other disorders that are commonly ascribed to the bladder, to consideration under the head of "diseases of the urinary organs, generally."

**Cause.**—Heat and inflammation of the kidneys communicate this effect to the ureters and bladder. It may be inflamed also by the irritation of stones, or gravel concreted within it; or the excessive labour imposed upon it by the greater access of diabetes, after these have passed off.

**Symptoms.**—Frequent desire to stale; the bladder contracting upon every drop of water, almost, that finds its way into it. A quick, sharp pulse, and small, accompanies, if it has not preceded inflammation of the bladder; yet bleeding would not be proper in this case, as it is the poorness of the blood which brought on the diabetes that caused the inflammation. When, however, this symptom has not preceded the inflammatory, the pulse will be more full, and bleeding to an amount proportioned to the state of the pulse (see page 179), would then be necessary.

**Remedy.**—A slightly purgative ball should of course follow the bleeding, but employ neither in the extreme. Give the cooling decoction recommended in general fever, at page 202; and administer clysters of the same, two or three times in the day. Should great heat of the region of the bladder continue, notwithstanding these remedies, give the
fever powder, No. 2, at page 190, and afterwards the same made into a ball, daily.

DISEASES OF THE URINARY ORGANS.

Besides the foregoing main diseases of the kidneys and bladder, there are several other conjoint affections of the same organs, or parts dependant thereon, which require notice, and demand attention, while we examine the distinctions that ought to be drawn between the one set and the other. Mistakes as to the actual seat of disorders are more dangerous than the unskilful administering of medicines, for these might do good by accident, but the former we know never can be applied properly: the better the "receipt" may be, the worse for the horse. Few of these lesser diseases are original, but arise from some defect or ill-cured disorder in the other parts of the animal's system. They may be considered under the heads—1. Diabetes, or excessive discharge of urine. 2. Bloody urine. 3. Calculi, or stone. 4. Strangury, or collapsion of neck of the bladder. 5. Suppression of urine, already mentioned. Well aware that the ingenuity of some doctors has enabled them to subdivide these, and to augment the number of diseases incident to the kidneys, ureters, and bladder; but, omitting these, and those which attach to the organs of generation in breeding animals, and also those seated higher up, we shall merely mention the communication of acute pains to the more vital parts, by means
of the emulgent and vena cava, to the heart itself. This last event, however, is so immediately the precursor of dissolution, that no other benefit can arise from the doctor's skill in this respect, than bidding him to cease his efforts, to forbear to torture the expiring patient, and to preserve his medicines for a less forlorn purpose: the pulse, by its extreme languor, tells when hope itself must resign its place.

**DIABETES, OR, EXCESSIVE STALING.**

The cause of animals discharging great quantities of urine cannot in every case be traced to its right source; but one thing always happens, namely, irritability of the bladder, by reason of the absence of the mucous secretion that is to protect it against the saline effects of the urine: see page 158. A defect in the mucous secretion of the whole system succeeds the disorder termed molten grease, and the irritation just spoken of soon communicates to the kidneys, which are thus compelled to secrete urine to the utmost extent of their power, and to send it forward to the bladder. To an impoverished state of the blood, arising mostly from the use of strong medicines for the cure of inflammatory diseases, leaves more of lymph than of serum in the vital fluid, with an accelerated tendency to increase that baleful difference—may be ascribed the chief cause of this obstinate disease. Bad dry provender, with ill-usage, and the denial of green food, in season, have a similarly evil effect on the blood.
Symptoms.—Of course, the most obvious is the discharge whence the disorder derives its name, being frequent, and in very large quantities. At first, the water is colourless, but occasionally comes off like puddle. Constant craving after water, a staring coat, evident weakness, and weak quickened pulse, succeed each other, and increase as the disorder is suffered to proceed unchecked.

Cure.—Change the animal's diet, whatever that may have been. If the horse be labouring under the remains of some ill-cured disorder, attend to that first, and by removing it, the excessive staling, which in that case is but an effect thereof, will also cease. Give vetches, grass, sodden corn, water in small quantities and often. If the pulse be higher than ordinary, give the fever powders, pages 189, 190; and when the number of strokes per minute is reduced, let the corn be given dry, and resort to bracing medicines. In slight attacks, as well as for the less robust animals, the various preparations of bark will be found sufficiently tonic.

Tonic Ball. No. 1.

Cascara,  
Gentian root,  
Powdered caraways,} of each 1 scruple,  
with treacle sufficient to form the ball for one dose.  
Give morning and evening.

In the more formidable cases, where greater strength or more tedious symptoms require to be combated, give the
Tonic Ball. No. 2.

Venice turpentine, 1 scruple,
Sulphate of copper; } of each 1 drachm.
Ginger, powdered,
Mix, with liquorice powder sufficient for one dose, and give twice a day for two or three days. After this, a return to the use of No. 1. would be desirable, until the disorder is subdued. Should costiveness ensue, give a clyster, which will also relieve the irritation of the parts; castor oil, one pint, must also be administered, if the costiveness appears obstinate.

Above all things, the horse-owner should avoid the use of such excessively ignorant prescriptions as are recommended, in this disorder most particularly, by every village quack: they are mostly the horses of hard-working people that are attacked with this disorder, and those people more than any other lie open to this kind of advice.

Incontinence of urine is of the same nature as the last-mentioned, only differing in the discharge being involuntary, and in the amount, or quantity produced. The disposition to stale frequently, or the urine coming away with scarcely an effort, proves that great irritability of the bladder is the proximate cause, and we may infer that the quantity would be greater if the animal had more in his system. For this feature of the diabetes attacks only old worn-up horses, in whom the quantity of blood is small, and its course slow. Diabetes of the younger
animals sometimes terminates in this mode of producing water by driblets and in small quantities, but to which the moderns have given a distinct term, though both are the same disease; a small degree of inflammation prevails when the animal is greatly affected with incontinance. See page 292.

The treatment should be the same, nearly, as directed at page 294. Give occasionally the tonic ball, No. 2, page 201, for two or three days. A run at grass for a week, and generous feeding afterwards, generally complete the cure, no other obstacles intervening.

BLOODY URINE,

As already said, is but one feature among many other correspondent symptoms of inflamed kidneys; and the only reason why we deem it worthy of separate notice is, that real "inflammation of the kidneys" is not always present when bloody urine appears, especially when no other symptom thereof accompanies this single demonstration of disorder. Its causes may be traced to excessive labour, as drawing in a cart or waggon, whilst a slight cold of the kidneys may obstruct their proper action: the office of separating the blood from the water is in this event performed with much difficulty, and of course imperfectly; and small portions of the former, instead of ascending towards the heart, descend to the bladder with the urine, while the animal is straining every nerve and vein.
Rest and a cooling diet are the best remedies for this apparent affliction. Should tenderness of the kidneys be evinced upon the touch, or other symptoms of augmented pain appear, give the *Tonic Ball*, No. 2, page 201, occasionally employing No. 1 instead: the *alternation* will be found beneficial. If these symptoms increase, (which we should not apprehend), then, of course, the attack must be met with strong appropriate remedies. But we have never known one case of bloody urine out of several score, wherein the *appearance* thereof having ceased with the *day of rest*, but comes on again with hard labour, that did ever terminate in genuine inflammation of the kidneys: it will return at intervals (upon hard work) during the animal's whole life, probably, without any further ailment attending it.

**CALCULUS; or STONE IN THE COECUM, KIDNEYS, URETER, AND BLADDER.**

When we consider for a moment the vast circulation that passes the (liver and) kidneys, there to undergo separation, as before fully described in the first book; and recollect, that hard extraneous substances pass through these organs, and find their way even into the blood, our astonishment ought to cease at discovering earthy particles, often hardened into stone, in some one or other of those parts.

*Cause.*—The first particle that is deposited, or
left behind, is no doubt very trivial, as the *bisection* of many such stones most amply proves. Want of vigour at the time of its access, and the consequent inability to expel the intrusion, appear to be the immediate cause of this otherwise inscrutable disorder. Subsequently, other congenial materials reach the original evil, mostly in the liquid form, and thus add to its size, increase the number of striata, and heighten the danger. The water that is drank by quadrupeds is abundantly impregnated with fit materials for generating calculi: soft river water, and that of turbid pools, convey the softer or earthy particles into the animal's system, whilst that drawn from springs contains the elements for forming stone, as perfect as any geologists find in the strata of our earth. The softer kind of these concretions are found in the blind gut, or *caecum*; the harder, or stony kind, in the other *viscera* above named.

Heat is the power that separates these elements, and hardens each additional lamina that has accrued, or grown over the preceding, from time to time, as the animal may have been exposed to *drink* so impregnated. This is visible on the section of those stones which have been found in horses and other animals, and preserved by the curious, and cut in two by the lapidary. Every such concretion so found, of whatever nature it may be, exhibits in the centre the *nucleus* or commencement of the evil, which proves itself to have been either originally stone, or some soft substance,
as a bit of chaff, hardened by the heat; but much oftener it presents a perfect pebble, that must have been borne along by the force of the current, and in the cleansing function of the kidneys got detained and deposited there. If not entangled, as it were, in the cellular membrane of this gland, such a pebble will detach itself occasionally and descend through one of the ureters into the bladder. For full information as to the structure and functions of these several viscera, the reader is again referred to the second chapter of book the first, which treats alone of such matters; as regards the cæcum, at page 138; the kidneys, at page 152; the bladder, at page 158.

One original cause of such concretions has been ascertained beyond contradiction, and as the information may prevent its recurrence among a numerous class of horse proprietors, we quote our authority much at large, by way of preventive advice, seeing that a cure is at present beyond the reach of art; remedies worse than useless. Let us hope, notwithstanding, that the mite which is here contributed may not be thrown away, but incite some future close observer of nature and her ways to add hereto the result of his own inquiries, and so increase the sphere of his utility in one respect, since imperious circumstances have contracted it in another and more obvious line of his profession—the desire of gain.

Millers' horses are most liable to contract this disorder, and for obvious reasons: being large heavy
animals for the most part, their owners opulent, if not rich, and grain and pulse ever at hand, dry food is invariably given to them with a liberal hand. To render these substances more agreeable, to hasten digestion, and thus produce a fine coat with a well-filled carcass, their corn is passed through the mill, the beans also are usually broken; and, thus pampered, they eagerly devour the ready feed, and with it whatever extraneous substances it may have acquired in the process of grinding. These are not few in quantity, it seems; for such articles are invariably ground between stones of a soft nature, that easily part with their rough surface, and these stony particles all find their way into the stomach and intestines; some, here and there, pass on through the circulation, by means that are neither uncertain nor inscrutable in the minds of those who have studied such subjects, and will refresh their memory by turning to what is said thereon in the second chapter of the first book.

Dr. Withers, of Newbury, Berks, having many years before given to Dr. Hunter a large intestinal stone, which proved fatal to the horse whence it had been taken, communicates to the Medical Society of Crane Court, London, a similar circumstance which had come under his observation—both being cases of millers' horses. He then describes “the case of a very valuable horse belonging to Mr. Andrews, another miller, which lay ill of the colic,” as the owner supposed. “I told him (says Dr. Withers) that if he would examine the intestines
after death, he would most probably find a large stone, which was the cause of the horse's illness." This, the miller, of course, neglected to do; but his dogs made the discovery for him: it was a large round stone, broken, from which circumstance, we infer that it had been at first a soft or earthy concretion, and proceeded from the caecum. Four such instances all together were remembered at the same mill; besides which, we hear of many others elsewhere: but, with characteristic negligence, the millers in no case thought proper to furnish the doctor with the when and the where found, nor does the doctor say why. If beans, &c. are to be given to horses broken, we may add that an iron hand-mill will be found to obviate the objection just raised against the millers' stone grinding. Such mills may be purchased for three pounds ten shillings of any iron millwright or vender in London. Yearsley, of High Holborn, has invented one which he "warrants not to clog," and thus obviates the only disadvantage under which they hitherto laboured.

All the symptoms of calculous deposite apparently resemble colic to the view of common observers, as in the case of Mr. Andrews' horses just quoted; the animal looking at his flanks, straddling when a kidney is affected, as if he would stale, which he does with great difficulty, and sometimes a little bloody. This last appearance also occurs when the bladder has been affected for any length of time, so that the anguish or acute pain had com-
municated to the kidneys by means of the ureters; in which manner alone blood could possibly have been produced in the celebrated case cited by two cotemporary writers from M. La Fosse, the elder. When stone resides in a kidney, it may be ascertained by pressure of the hand thereon: we will not exactly say the stone can be felt, for it lodgeth underneath, but the greater tension and enlargement of one kidney beyond the other, leaves that notion on the mind; besides which, the animal will shrink, or rather start, a little quicker than in case of "inflammation of the kidneys"—the symptoms whereof, as set down in a preceding page (284), the reader should consult in order to shape his practice accordingly.

Calculous or earthy deposits of substances in the caecum may be ascertained and distinguished from simple colic or gripes, by passing the hand along the lower part of the belly, as described in the first book, at page 138. While such an obstruction remains deposited in the depending part of that gut, no immediate danger or inconvenience is to be apprehended; but when the lump, by any means whatever, moves to the orifice, and obstructs its only passage, the most distressing consequences ensue. One of the causes hereof is the exhibition of heating, strong, or drastic medicines, which are usually given in cases of genuine spasmodic colic; and as the symptoms that attend both are alike almost throughout, with the exception just made, no mistake is more general, probably, than people
treating this disorder as they would *colic*, which of course endangers life by inflammation.

The *ureters*, it will be seen, are but of small capacity; and, in its descent from the kidney, whence it has been detached, the *stone* sometimes meets with an insurmountable obstacle: the irritation it thus occasions communicates to the adjacent parts; entire suppression of the urinary secretion is the immediate consequence, and mortification of the intestines and death ensues, without the possibility of relief. Indeed, the remedies that seem most proper do but accelerate the catastrophe.

Nature does more for afflicted animals of the lower orders, in such cases, than man can possibly effect, unless he confine his efforts to lowering the more acute symptoms. For, when *any* canal is *wholly obstructed*, we have reason to believe that a new passage is formed that carries on the functions as formerly. At least, this we know of the *large gut*, and as regards blood-vessels of the solids, by almost daily experience. High bred cattle, and consequently of *tender insides*, as well as those which are worked hard during such an attack on the intestines, do not survive this process of nature; with such horses, the catastrophe is more frequently accelerated by *medicines*!

Much perspiration attends the first hours of the suppression, and it affords evident relief; but painful efforts to void urine, which comes off in very small quantity, and ultimately ceases altogether; and then cold ears, cold legs, tremor, and
an alarming irregularity of pulse, precede but a short time the dissolution of the functions of animal life. This is the most dangerous species of disorder, arising from calculous deposite, we know of.

Whilst in the *kidney*, however, little danger to life is to be apprehended from the stone, unless the animal is put to severe work, so as to produce the symptom of bloody urine before described. They are mostly *fat* horses that die with stone in the kidney; in fact, *all* that we have ever seen or heard of, and these have been numerous; for we have long made a point of inquiring after such cases of *calculus*, where they seldom escape notice, *viz.* the horse slaughterers' yards, of which it is proverbially and truly said, that not a hair enters but is turned to profit, for we *buy* those very stones. The probability is, that when the stone detaches itself and descends into the *ureter*, the fat which partly enveloped it and the residue of the kidney had been withdrawn, through disease or poor living, and the membrane which supported both had divided. Some further observations on this part of our subject have been recently made, which will be worthy of public perusal; but these are not yet sufficiently mature to find place in this little volume, devoted as its pages are to matter-of-fact, and fair deductions therefrom, and wholly exclusive of argumentation or theoretic speculation. Nevertheless, in aid of what others may think fit to say in any other place (out of the spirit of controversy, which is still so rife among certain veterinarians) let us add, that only
one kidney is affected at a time, or one ureter; that the calculi found in either of these is invariably of the hardest kind, whilst those of the bladder are softer, and those of the intestines softer still, or little more than concrete earth. Lastly, that none of those horses we have found troubled with either kind of calculous disorder suffered under a second kind at one and the same time.

CHAPTER II.

EXTERNAL DISEASES.

Abscess and Tumour; Fistula, &c.

Swelling, with inflammation of the solids, the glands, or simply pustules on the skin, are all tumours, and have been divided into eight classes, but when lying deep, are termed abscess, to denote recession from the sight. Poll evil, fistula in the withers, quittor, warbles, range under this head; as do farcy, strangles, grease, and perhaps glanders, owe their origin to the same cause, viz. an ill state of the blood, its vessels, and the means of carrying on the circulation, as happens to all animals that gorge too much, or are fed badly. A few general observations on the remote causes hereof
seem necessary to a right understanding of each particular complaint.

All those disorders in common, together with several others, we have no hesitation in attributing their remote cause to constitutional defectiveness, at least; or incapacity in the function of circulation, better known by the homely expression, "a bad state of the humours," as before insisted upon, principally at pages 150—152; 171—178. Both series are referable to the same predisposing cause. That species of inflammation of the whole system which we have agreed to term fever, frequently terminates by concentrating its latent humours, and depositing the same critically in some fleshy part of the carcass or limbs, producing matter (or pus, which, with heat, constitutes the disease), that is corroding, sharp, acrid, and extremely offensive to the senses when brought forth, as it certainly is while yet confined in its cell, or cyst. These latter constitute the class of tumours termed bursæ mucose.

Whether abscess or tumour supervene, both have immediate connexion with blood-vessels of no small consideration, though the disorder may have commenced with the finer vessels (capillaries), as insisted upon at the pages above referred to; and hath been repeatedly proved: first, as regards tumours, these being probed, the patients have bled to death, with arterial blood. And secondly, in every case of abscess, in proportion as they increase in size, so does the patient's strength and quantity invariably diminish. When nature makes an opening
to the surface, after long-protracted illness, the patient is usually so exhausted, and the parts adjacent rendered so unfit to re-unite, that the constitution runs off at the orifice; in this case, life is seldom preserved, health never completely restored.

Tumours sometimes appear of tolerably large size, that become indolent, i.e. without feeling, and are movable with the skin. These are caused by the same evil state of the blood, or its vessels, and the inflammation or irritation having ceased at some time or other, the enlargement remains, though the connexion with the arterial system has long ceased. Although very unsightly, the animal feels little inconvenience from those protuberances: they receive the name of wens and may be taken off by dividing the skin, and pressing out the wen. It is then to be drawn forth with the forceps, usually accompanied by a long string, the old-school men termed a nerve, and the healing of the wound is performed by strapping down the skin with adhesive plaster; the cure is thus said to be effected by the first intention. The usual precautions of taking away the hair, and afterwards keeping the patient's head up for a few days, would of course be adopted.

The genuine tumour is soft and tender, and is contained in a membranous sac, or cyst, that has been likened to the finger of a glove, or to many of them, when it acquires the distinctive name of fistula. The case, or cyst, having been formed by the disorder, and matured by heat, acquires strength the longer it is suffered to continue unopposed,
TUMOURS, HOW ENGENDERED. [BOOK II.

seeking its way inwards, until the knife alone can afford relief. At the shoulder-blade, or scapula, the fibrous and membranous construction is exceedingly strong, whence fistula in the withers. Behind the noll bone, where the line 5 is intersected by A, in plate I, a body of soft muscular structure interposes between that bone and the first vertebra of the neck. Look again at page 40, &c. for setting on of the fore leg. Generally speaking, all swellings of a circumscribed nature are tumours.

Some objections which have been raised against the view we have taken of the origin of this whole series of diseases must not go quite unnoticed here. At the very commencement of this book (page 171), and without adverting to either set of controversialists, or indeed thinking at all of the dispute, we assigned a reason why the apparently triumphant proof of Mr. White, at his page 81, is no proof at all, but the contrary, as to the thickness or viscosity of the blood increasing with the continuance of inflammatory fever. Every writer on this subject allows, that the swelling and discharge of matter that frequently occurs after fever, or inflammation of the whole system, denotes the crisis or termination of that disorder; and insists that it must be considered as but an effort of nature to throw off something that is offensive to the well-being of the animal. The same happens often after "inflammation of the liver" has been reduced; but this kind of occurrence, though it adds nothing material by way of argument, leads us directly to the point at
issue. General inflammation (fever), it is allowed on all hands, begets *something offensive*, and so does partial or local inflammation of any organ through which the blood passes, particularly of the liver and kidneys, through which the whole mass gets filtered, as it were; and nature's efforts to get rid of this offence against her rules are evinced in swelling of the external parts, in the inflammation thereof, and subsequent escape of *the offensive something*, whereby a cure is effected.

All this is agreed upon by those who deny the necessary pre-existence of a general ill state of health, as well as by those who already know, or have yet to learn, that the liver, that acknowledged *cleanser*, permits much grosser materials to pass through it than those offensive matters, or *gross humours*, which we contend reside in the blood, and constitute disorder of one kind or other on the surface, or at least predispose the animal to acquire such, according as circumstances may determine it one way or the other. Seeing that such gross substances as bits of straw, chaff, &c. have issued from a vein on blood-letting, is it too much to concede the ultimate point that the feculent humours which constitute tumours, farcy, &c. may not in like manner find their way into the *circulation*, and be detained at that particular part which is rendered by some *accident* less capable of continuing the harmful matter in a fluid state? A blow, a gall, a ligation, or a bruise, are known to occasion this disability, and bring on disease in one of its varied
shapes. So does "a cold" produce fever in some animals sooner than in others, according as the circulation may be more languid, grosser in its particles, more predisposed to inflammation, or otherwise unfitted for its purposes; whilst some again acquire inflammation without any such accident or cold, the fever being lighted up occasionally by warm stabling alone, though the air they breathe may be perfectly innoxious in other respects.

How it is that those external diseases, enumerated at the head of this chapter, are generated, we will not here repeat: the reader may consult the principles upon which our opinions are founded in the twenty-ninth section of Book the First, page 95; to which we will here merely add, that the tumours we perceive or feel on the surface, which are not of a nature to break and discharge their contents—as farcy, grease, glands—are usually, if not always, accompanied by corresponding tumours on some vital organ, as the lungs, liver, heart. But single tumours, containing matter, as the whole tribe of fistula, &c. are designed to counteract and carry off obstructions, and all baleful affections incident to the organs just mentioned, and of all others: an owner ought therefore to deem himself happy, when some inscrutable long illness of the inside terminates in this manner. The appearance of these latter on the surface, may be taken as good assurance that none then exist internally; nor, indeed, any other disorder whatever, the natural strength of the animal system enabling it thus to
cleanse itself. Again, we may remark in general, that as it is the better bred animals that are most liable to affections of those organs, so is it the “country-bred cattle,” without any breeding in them, that mostly suffer these external attacks. To the reflection of every man of experience we refer this material point of dissonance between the two varieties of horse; which also serves to prove, that those horses which have great lumps of muscle at the parts liable to such attacks, are most disposed to contract local inflammation, and that puffing up of gland or lymphatic we call tumour of various kinds. Local inflammation alone, however, could not effect the evil, without some corresponding cause: else how comes it to pass that none but aged horses, that are heavy in the hand and slow in blood, readily contract fistula or abscess; young and lively horses, and those with some breeding in them, never? Once more,—if the disorder reside not in the blood, how does it come to pass, that a horse having contracted one species of tumour, he is never known to undergo an attack of any other species at the same time—and there are a dozen at the least? For example, give a horse the poll-evil, and see how little he will be disposed to contract the glanders.

Fleshy horses, those of the cart breed, and of indolent habit of body, are most liable to contract poll-evil, fistula, &c.; indeed, we might say, the ready disposition thereto is confined to that breed, though either could be inflicted upon higher bred
cattle, which might not be so predisposed by a bad habit of body, or by the gross humours before noticed. When the animals are young, and feed ravenously, the strangles carry off those humours; when youth leaves them, and more doltish habits come on, these humours appear in some other varied shapes: besides those diseases just named, the farcy, grease, and anticor, all come on from the same indolent habit of body. They are always gross feeders, and consequently lethargic in their movements, that acquire poll-evil; for they demand harsh treatment to keep them at their work, which frequently devolves into ill-usage, unless the carter possess the patience of Job.

Hence the duty of attending to the general health of such horses, as much as may be consistent with the avocations of the owner; of avoiding the infliction that is often the immediate cause of either species of ailment; and, these being discovered, of applying the necessary remedies for their instant dispersion—if the symptoms are mild, and thus promise success; a low regimen follows of course. But delay too often confirms the disease; it approaches towards maturity, and will not be repressed: then does the duty of "bringing it forward" to suppuration present itself as the only means of obtaining a radical cure; and we may add, that this is always the safest, the best, and the most certain means, when the disease yields not readily to the first efforts at dispersion. In ordinary cases of saddle gall, the swelling and heat will bend before an assi-
duous and early application of the lotion; not so easily, however, in case of "fistula in the withers," which lies deeper and is more obstinate. Least of all will confirmed poll-evil give way before the strongest repellents; or, if the resolution be apparently effected, the least external injury, or none whatever, will subsequently reproduce the disorder with more than its original virulence. Perhaps, in no part of the farrier's art has he the opportunity of evincing his judgment more, than in choosing the precise period when he will quit all attempts at suppressing the abscess or tumour, and set about bringing it forward to suppuration and radical cure; when he will also quit the low regimen which was proper in the first attempt, and adopt a more generous diet, that is better adapted to the painful discharge his patient will now be compelled to undergo, either by dint of medicinal applications or the knife.

Tumours in the more fleshy parts of the body, or under the belly, are far less dangerous or troublesome situations than on the parts just named; they also prove to be symptomatic of the actual evil state of the blood, of which they then form the crisis or point of cure, and therefore the repression of such (as recommended in other cases) should not be attempted; neither should the animal system be lowered, but the contrary. On the other hand, if the tumour appears near a joint, or just above it, as the hock, so as to impede its action, in which case it would soon assume an ulcerous appearance, by
reason of the movement of the long muscles of the limb in going, repression should then be resorted to with assiduity and skill. Artificial inflammation, excited upon the skin and cellular membrane, near the part, by means of blistering, or rowelling higher up, has the good effect of drawing off the heat and tension from the more important joint; nor does the animal by this application undergoing so much pain as he would were the tendon affected, whereby the limb would become irremediably stiff and useless; a disorder that is akin with another species of stiff-joint, spoken of elsewhere as simple Anchylosis, as will be found by consulting the Index.

CRITICAL ABSCESS,

Is that swelling or tumour which is occasionally thrown out on the body or limbs from no apparent accident, but what may be traced to that derangement of the system we call fever, and is sometimes attendant upon protracted inflammation of the liver, when the disease appears on the fascia of the muscles of the belly, on the jowl, or other glandulous parts.

The cause and the effect thus become manifest together; and when great tenderness is evinced upon touching the parts, nothing more is required, in ordinary cases, than to make an opening in the lowest edge of the swelling, and expressing the contents; the cure is effected by means of the common "digestive ointment," which is prescribed
under the article "Poll-evil," farther down. But
the proper time at which the opening is to be thus
made requires close observation. In general, this
may be ascertained by a change in the animal's
manner: he will eat more heartily as the matter
increases; which proves that the disease of his
habit has accumulated at this precise spot. He
should not be allowed long to remain in this state,
lest the offensive matter should penetrate inwardly
or laterally. If the disease is thus distinctly known
to proceed from the remains of ill-cured fever or
inflammation, poultices should be applied to bring
it forward to the surface, and the animal receive in-
creased feeds of dry corn, of beans, or sodden corn,
according to his former habits, in order to encourage
the access of matter: for nature, exhausted by the
violence or the continuance of the disorder, is in-
capable of expelling this last remains of the enemy,
and stands in need of support. Should the horse
have been lately laid up with fever, or for some
time past shown languor in his gait, and heaviness
about the eyes, or it may be concluded from his
recent hard labour and hard mode of living, that he
has been long ailing inwardly: in this case the
abscess being evidently a critical symptom of the
general evil state of his blood, nature must be as-
sisted in getting rid of the offensive matter; and for
that purpose bring the tumour to perfection by
means of a poultice. The head is most commonly
the seat of swelled glands, about the jowl.
FORM OF BANDAGES: [BOOK II.

\textit{Drawing Poultice.}

White bread, the crum of a 4lb. loaf,
Onions, chopped, 2lb.
Boil the onions in water, and pour the whole on the bread: mix to a tolerable consistency, and whilst blood-warm apply copiously to the parts in a cloth. Support the application by means of a \textit{bandage} of stout linen cloth, with ligatures tying over the forehead and across the poll thrice, as described in the annexed sketch. Some persons have recommended the use of a solution of gum, to render the cloth impervious to liquids, and \textit{caoutchouc} is with some Cockneys a great favourite.

\begin{center}
\includegraphics[width=0.8\textwidth]{poultice.png}
\end{center}

Should circumstances require a more extended application, or that the patient's restlessness might
rub off the bandage, let a more extended bandage be employed. For such an one, and as to further particulars, the reader may consult page 226, where a bandage for sore throat is depicted.

By those means the swelling will come to a head, and give signs of being about to burst, but which we have reason to believe never happens spontaneously by reason of the thickness of the skin. Apply the knife, or bistoury, as directed much at large in the case of poll-evil; give the like purgative on the same day, and lower diet is to take place of the above-mentioned. When it so happens that the opening has been made too soon, before it has accumulated sufficiently, the orifice may be kept open by means of a seton passing through it to the lowest or most depending side, and the running continued for several days, until it assumes a healthy appearance and the swelling subsides. This plan must always be adopted with the slow or sordid tumour, which will not come forward, though treated with the onion poultice, and even with a blister: then let the seton be applied, without cutting, changing it daily and soaking the tape in the irritating mixture, as in case of poll-evil, page 327. That other critical abscess, called strangles, comes under a distinct head farther down.

Deep-seated abscess, under the fascia of the muscles of the belly, is scarcely ever curable, being seldom discovered to the eye until too late to render assistance in bringing it to the surface by means of strong drawing poultices, as in case of obstinate
poll-evil. On passing the hand over the part, the animal may be observed to flinch from the touch; but this symptom is seldom attended to, and it makes its way inwards, bursts in the cavity of the abdomen, and kills the patient.

POLL-EVIL.

Causes.—Next to a diseased habit of body, as just above noticed, which is found to predispose a certain description of horses to contract tumours in various parts of the body, the poll-evil is frequently occasioned by a blow, or gall, of a very trivial nature, if it do not come on without this kind of excitement. The action of the head is very great with some horses, arising probably from an itching in the upper part of the cervical ligament, where it is attached to the vertebrae of the neck; and this causing irritation, we need not hesitate long in accounting for the inflammation that affects the muscle which interposes between it and the knoll-bone, in a cavity that is greater with some breeds of horses than others. This variance in conformation is exemplified in the whole length portrait of a skeleton which is prefixed to this volume, wherein the cavity that should form the seat of this disease is scarcely perceptible; whilst the small figure, inserted at page 68, to illustrate the uses of the cervical ligament, has this cavity of the usual extent. Of course, this latter would be still more predisposed to contract poll-evil than the former, which was a peculiarly
formed horse in another respect also; and it is more than probable, that if the two were to fall into an equally bad habit of body, whilst the latter might acquire poll-evil thereby, the constitution of the former would throw off any offensive matters that might accrue by some other means *. The reader will do well to turn back to the section referred to (p. 68), as well as to the skeleton [at A 5].

The wheelers, in a set of horses, will frequently throw back the head in warm weather, or after brisk work, at feeling the reins that run through their head-harness to the leaders: this motion is performed as the reader will have learnt, by the action of the cervical ligament, (see fig. page 68), the upper end whereof terminates where the ear-band rests, and, perhaps, pinches the part. Horses that are given to shy are likely to contract poll-evil when hanging back, and throw up the head with a jerk. But the most prolific cause of poll-evil is attributable to the low stable door-way, whereby the animal gets many a trivial hit at going in and coming out; next in point of frequency is that brutal mode of attacking restive horses about the head with the butt end of the whip, an evidence of ferociousness on the part of the offending carman that

* These might appear in shape of grease or farcy; but it has been generally observed that a disposition to farcy abates, if it do not subside entirely, upon the appearance of poll-evil. Again, horses that are most liable to contract "the grease" are precisely of the same disposition as those which are afflicted with tumours, &c. viz. of indolent habit, heavy in the hand, and slow of blood, fleshy and dull.
was much more rife in our younger days than at present. Pressure from the sharp edges of a new stiff ear-band has brought on poll-evil of an in-
veterate kind, within our own cognizance.

*Symptoms.*—At first the animal appears restless, throwing his head back and returning it to the former position, as if the effort had occasioned pain. Soon after, it droops the head, holding it now on one side; now on the other; appears dull about the eyes, and becomes sluggish in its move-
ments. In this state it continues a longer or shorter time (even weeks) as the violence may have been greater or less that brought about the evil; the time depending also in some measure on the height of the pulse—a languid system making of course the slowest advances towards bringing the abscess to maturity. This uneasiness of manner is accom-
panied by heat, swelling, and shortly by tension of the part, and increase in the pulsation. As it goes,
on, a disposition to flinch from the touch is evinced whenever the part is approached with the hand: if the evil be deep-seated, the swelling is wide, but not so high; but when nearer the surface, it pre-
sents a point, is circumscribed within a well-marked circle, and ultimately tells how necessary it is that the contents should escape, by a throbbing which may be felt at this *point.* Again, to ascertain that the *matter* is near the surface, apply two fingers alternately on the sides of the tumour, and the matter will recede from side to side. *Let it out.*

*Cure.*—At first this may be attempted, in the
earliest stages of the disorder, by repression or dispersion, provided the disorder be not *deep-seated*, near the bone; which will be the case if it has been brought on by violent means, or it be a second attack, when endeavours to repress it would be vain indeed. On the contrary, if we can trace the cause to a hurt of no long standing, or of trival import, and we know the horse was in good health before the swelling took place, then our duty is to put back the *evil* into the animal's system, and work off its bad effects by *physic*. Foment the part well with bran and water, warm; rub it dry with cloths, and apply the

_Embrocation._

Spirits of wine, half a pint,
Camphor, 2 drachms,
Goulard's extract of lead, 1 drachm.
Mix, and apply the same two or three times a day, gently rubbing the part as much as the animal can bear. Give, also, at the same time the

_Alterative Ball._

Aloes, 4 drachms,
Castile soap, 2 drachms,
Calomel, half a drachm.
Mix with mucilage, and give one each third day, provided the embrocation is applied so long.

During these applications, a cooling regimen should be observed, the feeds being reduced to half the usual quantity of oats, and ultimately discontinued altogether. There will be no propriety in
clothing up the patient, nor need he be exposed to cold air, if it prevails. When the disorder has been brought on by simple compression of the ear-band, and is recent, we have never known the foregoing treatment to fail; and in cases of vigorous constitutions, the swelling, heat, and tension have been reduced so quickly (i.e. in four or five days), as to leave certain careless observers in doubt whether the animal had really laboured under a genuine attack of poll-evil.

Remove the halter, and if the animal be put to work, contrive to keep back the ear-band. A good and valuable embrocation will be found in simple vinegar three or four times a day, or that kind termed alegar in the north, or the sediment of very stale beer. Old verjuice answers the same end; and all this kind of embrocation must be laid on warm, by means of cloths soaked and applied repeatedly.

*** The same treatment and observations will apply to all the other species of abscess in its milder state, viz. fistula, warbles, quittor; but of these let us speak more particularly under their respective heads of information.

Second method of cure.—Very few cases present themselves to recollection of even recent poll-evil, that would admit of being completely dispersed, and a radical cure effected, by any means whatever; and it is due to candour to acknowledge, that some of the more stubborn attacks were found to have relapsed after a while, which proved that
the cure so effected to all appearance was not radically good, but had left a violent predisposition to renew its ravages afresh. Probably the time of inflicting the injury had not been accurately marked, nor its degree ingenuously reported to the owners in those cases of relapse.

However this be, when the disorder is found to baffle the endeavours employed to disperse it, the whole course of proceedings must be changed, as before hinted in the general observations on this topic. Instead of putting back the swelling by those means, we must pursue a direct contrary course, in order to bring it forward: the mode of feeding must be changed along with the medicines that now become proper to procure suppuration, or a discharge of the offensive matter; a full habit being mainly conducive thereto, and proving how closely connected is this disease with a gross habit of body, which in all fleshy animals superinduces a diseased habit, vulgarly but accurately termed "full of humours." After having found useless your efforts to disperse the tumour, or mayhap, finding at the first view of it, or by the first touch, certain symptoms that prove it ought never to be dispersed, the practitioner will of course seriously set about permitting, or forcing, the offensive matter to escape. Every hour's delay in putting this resolve into practice serves but to render the ultimate cure still more difficult and hazardous; for the evil is all this while extending its baleful effects inwards and sidewise, and forming around it, in every direction,
the fistulous case or cyst before spoken of, which is a film, or skin-like substance, formed of *cellular membrane*, thickened by the heat of the disorder. (See Book I. Sect. 27.) In this event, the tumour has become decidedly fistulous, *and is to be treated as such*, when the great length of time it may have been suffered to make head, and its now extended surface, warrant that conclusion. The knife is almost the only remedy, notwithstanding a *superficial tumour* will in some cases break and discharge matter of itself; this, however, never happens with the *deep-seated abscess*, which lies close to the bone, and destroys not only *it*, but the muscular substance of the poll, and the end of the cervical ligament also. In these series of abscess or fistulous tumour, nothing but *the knife* can ever reach the disorder, and it must be employed fearlessly, but with a commensurate share of skill, after the skin has been prepared with fomentations, &c. Let the parts be softened and *drawn* with poultice of oatmeal, put on luke-warm twice a day; and if the effect be not visible to the eye and touch, as before described, increase the powers of the poultice by the addition of onion chopped and mixed with the poultice whilst warm. Or, a mere change may be adopted, and a bread poultice applied instead; for, notwithstanding oatmeal is stronger, yet have we occasionally found the milder have more effect when the former had not succeeded entirely. The poultice should be provided in sufficient quantity to cover the whole swelling two inches thick at least,
having a small quantity of sweet oil, hog's lard, or oil of turpentine mixed therewith. Fix it on by means of a contrivance that is sufficiently explained by the annexed cut, in which it will be seen that the girth is to have a web breasting, to which the lateral corners of the cloth are to be attached by broad tapes, as was explained in other similar cases at pages 226 and 316.

The bandage is represented rather longer than requisite, under the presumption that it may occasionally be applied to other affections, farther back; a prolongation of the bandage may be affixed at either end, plain or plaited, according to the amount of the swelling, as is evident would be required at the poll itself.

When the symptoms above stated inform our senses that the matter ought to be so "let out," an opening is to be made the whole length of the
abscess, a little below its centre; taking especial care that the knife do not pass cross-wise, lest the attachment of the cervical ligament to the first vertebrae of the neck should be severed; in which case the animal would droop its head ever after, as may be learnt by consulting its construction, at page 68. On the escape of the matter, after ascertaining by a probe whether it runs in pipes, or sinuses, this way and that, or with small bits of diseased fibre or membrane stretching across the cavity, so as nearly to divide it into unequal parts—let each be just touched with the knife or scalpel. There is no propriety in the old practice of squeezing out all the offensive matter from this kind of abscess, although it be very proper in that deep-seated sort where no pipes, nor the small cavities just spoken of, are to be felt or seen, for the following reasons: the first mentioned kind have the case or cyst before described, which contains all the matter, and if this be laid open before the evil be sufficiently ripe, it does not come away entirely. This, however, the operation effects in two or three days, if kept running by means of a seton, or other contrivance placed at the orifice; but the application of tow, or any other substance, that obstructs the escape of this matter, is ever to be avoided. On the contrary, when the abscess is very deep, reaching to the bone, which may be felt, and presenting but one large cavity, then the matter should be expelled by pressing gently on two sides of it at once. Let the lips of
the opening be dressed the first time, and as long as it may be found necessary to keep open the wound, with any ointment hereafter mentioned, on which has been strewed sulphate of copper, powdered. Should the lips adhere together, or appear much diseased, wash with muriate of ammonia, taking care it does not run upon the sound parts, nor into the cavity. In either case, wash off the dead parts with warm water, before each new dressing is laid, sponge it well and dry, after inserting the probe on every side into the fistulous sinuses, and continue this mode of treatment until the parts assume a healthy appearance.

The seton should never be neglected in bad cases of either description, but be introduced at the lowest or most depending side of the abscess, after being wetted with the following

**Irritating Mixture.**

Spirits of wine, 2 ounces,
Corrosive sublimate, 1 scruple;
Mix and saturate the tape therewith daily. This will keep open the orifice until the offensive matter has run off, and is succeeded by the more healthy issue of a thicker consistency, and nearly white. On this appearance the seton is to be withdrawn, and the parts dressed with the digestive ointment, the animal physicked once or twice with a moderate purging ball of six or seven drachms of aloes for a heavy animal, and the cure will complete itself with the usual dressings, viz.
Digestive Ointment.—No. 1.

Yellow wax, Rosin, 
Burgundy Pitch, 
Turpentine (common) 4 ounces. 
Linseed oil, 20 ounces.

Dissolve over a slow fire and spread upon leather or stout linen cloth sufficiently large to come over the undiseased region of the evil, after the wound has been well cleansed. Fresh dressings hereof should go on daily, but in no case until the matter assumes a healthy appearance, which it never can be brought to, unless the whole recess has been reached with the knife, or by the operation of "the scalding mixture" of the old school of farriery. This remedy, so applied, though at variance with our modern notions of pathology, has been adopted by the collegians of St. Pancras, and with good reason, for it never fails to effect a cure, by effectually cleansing away the diseased parts. Three several mixtures are adopted in different parts of the country—the Hertfordshire and midland county farriers employing No. 1; No. 2 is that recommended by Gibson; and No. 3 is Ryding's.

Scalding Mixture.—No. 1.

Tar, 
Mutton suet, of each 2 ounces. 
Rosin, 
Bees wax, 1 ounce.—Melt slowly, and mix in
Spirits of turpentine, 2 ounces.
Verdigris, 6 drachms.
Mix and pour into the orifice _hot_, and close it with stitches. The next two have the recommendation of being more scientific, and are withal better adapted for penetrating into the sinuses.

_Scalding Mixture._—No. 2.

Corrosive sublimate, \[ \begin{align*}
\text{Verdigris},& \quad \text{of each 2 drachms.} \\
\text{Blue vitriol,}& \\
\text{Green copperas, } \frac{1}{2} \text{ an ounce,} \\
\text{Honey, or } \text{Ægyptiacum, 2 ounces,} \\
\text{Oil of turpentine, } & \\
\text{Train oil,} & \\
\text{Rectified spirit of wine, 4 ounces.}
\end{align*} \]
Mix, and apply as before directed. The difficulty of retaining this last in its proper place, is its only defect; but Gibson appears to have prescribed a quantity sufficient to allow for spilling a good portion. This fault, however, will be obviated in great measure by the improved bandaging, recommended at page 325.

_Scalding Mixture._—No. 3.

Oil of turpentine, 2 ounces,
Verdigris, 1 ounce,
Ointment of yellow resin, 6 ounces,
Mix and apply as above. In using any of these hot mixtures, a piece of tow should be so placed as to surround the orifice and prevent its running
over the sound parts—which would be injured thereby, as would the operator's fingers, &c. if he neglect the proper precautions. These he should not fail to take, as regards the acrimonious discharge from the abscess, as absorption thereof might take place at the root of his nails; so, if the discharge be allowed to rest upon the sound parts of the horse, it will be found to corrode and produce ulcers.

Frequently it happens that a second application of the "scalding mixture" becomes necessary, for their cases were always very bad ones. In this event, opportunity is afforded of employing two prescriptions in succession; but whichever is first adopted, let it remain undisturbed from sixty to seventy hours, if the stitching do not sooner burst. Sponge out the parts with water; cleanse away the adjacent filth, and either repeat the same or proceed at once to the cure—a determination the doctor will come to, according as the rottenness may have sloughed off, and the inside of the abscess may present a healthy appearance, or otherwise. If it be quite clean, the adhesion of the parts will follow with very little further care than applying the digestive ointment according to the receipt in page 328—or the following

*Digestive Ointment.*—No. 2.

Common turpentine, 4 ounces,
The yolks of two eggs.—Mix these well, and add
Myrrh, in powder, 4 drachms,
Mastich, 2 drachms,
Tincture of myrrh sufficient to bring the whole to a proper consistence.
Should the cure of the wound proceed too fast, the over-luxuriant granulations of new or proud flesh must be touched with caustic.

But, notwithstanding all that has been said, it sometimes happens that a totally different course becomes necessary, when abscess in the poll is connected with another disease arising from the same vitiated state of the animal's system, and the remedy for one of these will cure the other. Farcy is the correspondent disease here alluded to, or rather say a tendency to farcy, visible in certain scanty lumps or tumours on the body and legs: these will be run off sometimes by means of a copious discharge at the poll. Occasionally, however, the farcy is of too inveterate a description to run itself off; this proves that the whole mass of the animal's system requires correction, and that it must be treated with medicines proper for the farcy, as well as the local affection which has obtained the name of Poll-evil. We have agreed to call this disposition to contract diseases, the humours, for want of a better term; which we have consented to illustrate, by allowing that it may be "the humours diverted from their healthy course," whereby the animal system is vitiated, and lies open to incur the first attack of
any sort which may supervene. We strongly touched upon this topic in Book I., and at page 172, to which probably the inquiring reader will turn, as well as to the Index, under *humours, secretions*, where he will become convinced with us, that poll-evil is often no other than the *critical abscess* of farcy; which farcy is a disease of the system, and is also correspondent with *glanders*, as poll-evil is with *quittor, warbles, vives, &c.* An able writer agrees with us, mainly, in this view of the subject, though he disorders his own point by a salvo that means nothing. He says, "the poll-evil is sometimes connected with a disposition in the habit of body to farcy; this may be known by the animal appearing generally unhealthy in his coat, by the tightness of his skin, and also by small lumps or swellings in different parts of his body, and particularly on the insides of his legs. When it is ascertained, therefore, that the poll-evil arises chiefly from a *disposition to farcy*, the mere operation of opening the abscess, and using the dressings usually recommended, will not prove sufficient, without the aid of medicine given *internally*: because the *abscess*, not being then a local affection arising simply from partial injury, it will be necessary to correct the general habit of body, before a cure can be effected." The medicines best adapted for this purpose will of course be found under the head of "Farcy," a few pages farther down.
FISTULA IN THE WITHERS.

Cause.—Although closely resembling the poll-evil in so many respects as to seem the self-same disorder arising from precisely the same causes, but differing in situation only, we must here premise that some other distinctions are proper to be taken, which it will be necessary to keep in mind. As we have just now seen, poll-evil may be produced without external violence; but this never happens with fistula in the withers, which is always brought on by external injury—namely, the galling of the saddle: in the first case the tumour frequently turns out a simple abscess, in the present case never, but becomes fistulous at its very earliest stages. This arises from the quantity and great strength of membrane which is found in the shoulder and whole forehand of the horse, in the cellular structure whereof the offensive matter finds an easy receptacle, and spreads its ravages from side to side and inwards. How this operation of nature is performed, the reader is instructed in the first book, at sections 26, 27, and at pages 51 to 58; the setting on of the foreleg to the body, is described as affecting this particular disorder, as well as the tread, pace, and form of going. We have also descanted at large in the general introductory observations on this whole series of disorders, on the distinctions proper to be kept in mind between one kind of tumour and another, how they are formed, and what description of horses are most
liable to this or that species of the disorder, page 305 to 313.

The symptoms are most obvious to the touch, as in all inflammatory tumours, the animal flinching when the hand is passed over the shoulder from the mane backwards. But the ill-formed saddle, or one that fits the particular animal like nothing; or a proper fit, that is so badly girthed on, that the poor beast may be perceived going in great pain, shall be set down as the symptom of all symptoms that the animal is destined to contract this particular disorder of the parts so injured. Sometimes the horse tumbles down, or seems to trip frequently, which should admonish its inconsiderate rider or driver, that his carelessness is very likely to cost him a broken neck.

Cure.—As soon as the journey can be brought to a close, which has been thus improperly pursued, remove the cause and bathe the part well with the cold saturnine lotion, and when the saddle has undergone the proper alterations, the journey may be pursued, if necessity demand such an exertion.

Cold Lotion.

Subacetate of lead (goulard), 2 ounces,
White vinegar, 4 ounces,
Water 3 quarts.—Mix; and apply with a sponge.

Should not this application avail him, and the horse still evinces pain at the touch, with increased heat and tension, and swelling of the part commence, the disorder is confirmed, and if not re-
pressed in its very earliest stages, suppuration must ensue. Let it be taken in time, however—that is to say, in the course of a day or two, or a week with healthy active horses, is not too long—and the heat and inflammation will be reduced by employing the embrocation, recommended in incipient attack of poll-evil, at page 321, and giving at the same time the alterative ball there set down. Success more generally attends this first method in the present kind of tumour than in that to which we have just referred, viz. poll-evil; but this method of curing both is so exactly similar, that it would be a waste of words to go over the same grounds again, or make the same observations which we thought proper to set down under that head of information. At page 321, the reader will perceive, that when he is attempting to repress the tumour and allay the inflammation in its earliest stages, he is to employ a cooling regimen; that when the disorder has been brought on by a trivial cause, this method of cure seldom fails, if taken in time; and also that fistula is easier prevented hereby than is poll-evil. "However this be, when the disorder is found to baffle the endeavours employed to disperse it (as was before observed), the whole course of proceedings must be altered;" the regimen, or feeding must be higher, the parts encouraged to collect matter and come to the surface, instead of making inroads upon the adjacent muscle and bone, which it will effect more hideously as the animal may be afflicted with a gross habit of body.
After having found all his efforts useless, the practitioner will change his plan, and force the matter to escape as soon as may be: for the disorder is every hour extending its baleful influence. For this purpose the knife is to be employed when the tumour is sufficiently ripe, which is a state it may be brought to, by means of the poultice application. Of these, two or three kinds were prescribed, with the method of fastening them on, but in this latter respect, a material difference arises in consequence of the different shape of the parts. The bandage in this case must be allowed to come farther back, and be there detained by tying the tapes short behind and lengthening the front ones. See figure at page 325.

Fomentations of warm water, in which cloths have been steeped, slightly wrung out and applied to the parts, will be found highly serviceable, and may precede the application of poultice. When by these means the tumour appears ripe, open the most prominent part with lancet or bistoury, and insert a whalebone probe to ascertain the direction that the fistulous sinuses or pipes extend, in order that these may also be laid open, and the whole matter suffered to escape. In some cases a stiffer and larger probe may be employed, and when a sinus lies favourable, introduce the probe to the bottom and cut down upon it, its whole length. But as to the lowermost sinus, when it tends towards the shoulder, so as to interfere with the action thereof, the knife is not to pass through it, but a seton is to
be inserted in its lowest or most depending part, so as the matter may escape through.

As directed in the previous case of poll-evil at page 326, the knife should be fearlessly applied in severing any small bits of muscle that may appear to grow across the cavity; a touch of the knife will be sufficient for any purpose, as by keeping open the lips of the wound, all that belongs to this diseased part will slough off, and should be wiped away, as before directed, every time new dressings are applied. Let the seton be soaked in the mixture of corrosive sublimate and alcohol as directed at the page just referred to; and in the worst cases apply either of the scalding mixtures in the manner mentioned at page 328, and repeat the same if the first dose does not accomplish all that is desired.

The operator in this case will not fail to use the proper precautions as regards the application of those scald-hot remedies, nor neglect to remove the matter that is discharged from the wound, in the manner set forth at page 326. Most frequently, the lips or edges of the sore are thickened by the heat and acrimonious nature of the discharge, and assume a very inflamed and ulcerated appearance; this should be reduced by the knife or caustic, or it becomes so luxuriant at times as to close the orifice, and to cause a renewal of the fistula, in which case you have all your trouble to go over again. At Alfort, they have a very neat method of cleaning
out fistulous ulcers, by rolling up *pledgets of linen* cloth, the edges whereof have been scraped out thin, so that when introduced dry to the bottom of each sinus or pipe, and being twisted round, it brings forth the offensive matter and any residue of blood which may have got into them during the operation. They also employ *gentian root* to keep down the swelling or thickening of the lips of the sore. The healing is not to be suffered to go on too fast, nor until all the offensive matter has been expelled, and a more healthy discharge, whilst it manifests the change that has taken place, and warrants your closing the sore. *Blue stone* spread on any plaster of digestive ointment will effect this; or take

Ointment of nitrated quicksilver, 3 ounces,
Oil of turpentine, half an ounce.

Mix, and apply as long as it may be found proper to keep the orifice from closing, to which it will be ever too much disposed.

Something was formerly said about scraping the bone, whenever the long continuance of the disorder, its virulence, or the bad state of the horse's general health, hath been such as to affect the fine enamel of its surface; but this part of the operation is rather showy than useful, as the rottenness so occasioned will come away as the discharge is kept up, there being a constant disposition throughout the whole system to throw off all such offensive matters.
QUITTOR

Is a disease of the foot, at the coronet, but is so decidedly fistulous, that we choose to treat of it in this place, rather than in the chapter devoted to the foot in general, that the student may more readily remember the general observations prefixed to this whole class of diseases, at page 305, &c.

Cause.—A tread which the horse inflicts on itself, for the most part, seeing that it generally occurs on the inside of the foot. This tread or bruise may either be inflicted upon the coronet, or lower down, by over-reaching, or even at the sole; by taking up a stone or other hard substance; also by a prick or blow in shoeing. According to our view of the construction of the foot, [Book III. chap. i.] and the manner in which the hoof is renovated by the supply of a glutinous secretion from below, ascending to the coronet for that purpose, it will be seen that the injury, however trivial originally, would occasion some of the finer vessels engaged in carrying on this supply to suspend their functions awhile; the detention of this secretion would of course cause a morbid affection at that place, and when at length it ascends to the coronet for the supply of new hoof, it would be unfit for that purpose. It remains there, and occasions inflammation, the formation of matter, and the whole train of fistulous symptoms, with a sore towards the hind part of the coronet.

Cure.—The sore is always very small, but ad-
mits of a probe being introduced, by which the extent of the evil may be ascertained, and this is generally very extensive and ruinous, according to the time it may have been allowed to make head. The probe will pass readily forward and backward to the whole course of the disease, and sometimes it will be found to have penetrated to the coffin-bone, everywhere forming sinuses or pipes, as in fistula in the withers. But in this case situation makes considerable difference: unlike the former, poultices are rendered inapplicable, whilst the employment of the knife or lancet is dangerous in the extreme. Besides which, the diseased part is already open, and seems to invite the only species of remedy yet known, in the shape of escharotics, that by irritating the case or cyst, which forms the sinuses, shall cause it to slough off. In slight cases, those which are found not to have penetrated deep, the simple application of a wash will prove sufficient; and may be employed in this manner. Dissolve blue vitriol in water, and charge a syringe therewith; this is to be discharged into the orifice, and suffered to remain, as much as can be retained. A poultice of bread and oatmeal is to cover the part, and the cure will be complete after two or three days. But, unfortunately for the owner and the animal, the disease is seldom taken in hand thus early, but is suffered to proceed until much stronger means become necessary. For this purpose, take a long narrow slip of thin paper, and moisten it with muriate of antimony; over this strewn powdered
corrosive sublimate, and roll up the paper, so that it may not be too big for the sinus or pipe which it is intended for. Generally it happens that the opening requires to be enlarged before this pledget so charged with the escharotic can be fairly introduced. Take especial care that the pledget reach the bottom of the pipe, cut it off close, and pass a similar one into as many sinuses as may have been ascertained forms the disease. As considerable irritation of the part will quickly ensue, a poultice sufficient to cover the foot should be previously got ready, and applied without delay.

In three or four days, the bandage being removed, the diseased parts will slough off, and a considerable opening presents itself, leaving a healthy looking sore. Let this be sponged off with warm water, and when dry apply tincture of Benjamin, which will effect a cure. A solution of white vitriol is used with advantage, especially when a disposition to secrete unhealthy matter is at any time perceptible. Physic the patient after the operation, according to the actual state of his bowels, the motion whereof will alleviate the pain necessarily attending the escharotic quality of the pledgets applied to the foot. If the horse's bowels be found in the ordinary state, give two balls on successive days, thus:

No. 1. Alterative Ball,

Aloes, \(\frac{2}{3}\) of each 2 to 3 drachms,

Hard soap \(\frac{1}{3}\) q

q 3
Oil of cloves, 6 drops,
   Calomel, 1 drachm;
Mix, with mucilage sufficient to form the ball for
the dose. This does best when the bowels may be
already relaxed, or the pulse quite up to their
highest healthy pitch.

No. 2. *Alterative Ball.*

Aloes, 4 to 5 drachms,
   Hard soap, 4 drachms,
   Oil of anise-seed, 10 drops;
Mix, and give one dose the day following the first
ball. If the urine be a little turbid, encrease the
quantity of soap to 6 drachms.

THE VIVES.

This is the term given to swellings of the glands
just under the ear, towards the angle of the jaw,
that mostly attack young animals. The tumour
is easily repressed or driven back into the system,
and by more simple means than those employed
in more inveterate complaints of a similar nature,
that show themselves in other parts of the body.
In some respects this disorder bears near affinity to
the *strangles.*

*The Cause of Vives* may be distinctly pronounced
"a cold," that prolific source of so many other
disorders incident to man and horse. *The vives*
usually come on after hard work and sweating, by
the animal being then exposed to a current of air,
or cold rain. The season of shedding the teeth, when the contiguous parts are unusually tender, is that in which swelling similar to *vives* pervade animals of any species. Nevertheless, it sometimes attacks horses at an advanced age, notwithstanding they may have previously got over the most healthful form of *strangles*, when we might reasonably suppose nature had ridded itself of a disposition to secrete any more such pestilent matter. Want of the usual head-clothing is then the immediate cause of *vives*. The violence deemed necessary in breaking colts also causes the *vives*, when the pressure on these *parotid glands*, at reining up the animal, irritates the parts.

*Symptoms.*—Swellings under both ears, generally, that occasion manifest pain when touched: the animal coughs more than one which has the *strangles*, and a difficulty of swallowing soon becomes evident. Stiffness or aridity of the neck follows, and the patient makes frequent efforts to swallow the *saliva*, which it is the proper function of these glands to secrete, but which they are soon disabled from sending forth by reason of the inflammation having choked up the orifice whence it issues. Of *Glands* generally, their construction and uses, the reader will find many instructive particulars in the first book, at page 92; these of which we now speak being called "the parotid glands," from their situation under the ears; and as they now refuse to part with their *secretion*, the watery humours flow from out the animal's eyes.
which he then partly closes, as if about to sleep. Similarly hereto, for want of the due supply of saliva from other glands of the mouth, inflammation of the gums takes place, producing what is vulgarly called Lampers, or swelling of the roof of the mouth near the front teeth. Sometimes the swelling of the parotid glands, if not assiduously subdued, continues a fortnight or longer, becoming more troublesome every day, and evidently occasioning very much pain; all this while the horse loses condition, is feverish, and at length so weak as to totter when he moves, even in his stall. Spreading downwards under the throat, they at length terminate in strangles, and are then to be treated as such.

The cure of vives that arise from simple cold is very easy, but not so that which is connected with a general bad habit of body; for, then the swelling and subsequent suppuration of the abscess must be considered as an effort of nature to relieve itself from something that is offensive to it, and must be treated as a disease of the whole system, nature having adopted this or that particular spot for demonstrating its offence. But we have already explained this interesting point of veterinary pathology, much at large, when treating of other tumours and abscesses, at page 305, &c. Often times it happens that the vives depend upon glanders or farcy, of which they are then a correspondent symptom, and will only subside or "go back," when the virulence of these are reduced. However, no harm can come of fomenting the part with
warm water at least; and after it has been well dried, clothe the head so as to keep off the air, upon the old principle of "remove the cause, and the effect ceases of course." Employ the bandage described at page 316; this will clothe the part sufficiently for any ordinary purpose.

Much of the pain and tension of the tumour will be alleviated even by this treatment, and a slight attack will be removed by following it up with fomentations of marshmallows; or, anoint the parts with ointment of marshmallows, and cover the head as before. A bread poultice affords relief, and bleeding in stubborn cases of simple vices is often necessary, with purgatives. Indeed, the body should be opened, whether we bleed or no: always leave open the main road for such humours to escape by. This alone will carry off a recent attack, provided the head clothing be kept on at the same time, nature performing the remainder by absorption. To assist nature, employ the following

*Lotion.*

Sal ammoniac, half an ounce,
White vinegar, 6 ounces,
Goulard's extract, 1 ounce;
Mix; and rub the part well twice a day.

Low diet, a plentiful supply of water gruel, and a change to bran mashes, in which an ounce of nitre is dissolved daily, will reduce that thickened state of the blood which ever attends this species of tumour. But, as in the preceding cases of tumour (poll-evil and fistula), it is sometimes found impos-
sible to remove the *vives* by those means or any other; *matter* is formed, the tension and inflammation continue upon the increase, and plainly indicate that suppuration must ensue, and all our labour is rendered vain, if it ought ever to have been so employed at all. In this event, apply a meal poultice, restore the animal to his ordinary diet, and promote suppuration, which effects the cure in the same manner as in all other cases of abscess mentioned before. Pages 292 to 300, 315, &c.

*False vives*, or imperfect ones, that are hard and insensible, sometimes cause a good deal of needless trouble. They neither come forward nor recede, do not seem to cause any particular pain, but still continue an *eye-sore*, give reason to apprehend disagreeable consequences, and always prevent an advantageous sale of the animal. Stimulating embrocations are well calculated for reducing these hard tumours, and the blistering liniment, made of cantharides and oil, never fails.
CHAPTER III.

EXTERNAL DISORDERS: DISEASES OF THE GLANDS.

Purulent Tumours.

Strangles, Glanders, Farcy, Grease, as they owe their origin to the same predisposing cause so evidently, that the appearance of either is good assurance that no other disorder is then to be apprehended—neither of the above, nor either of those treated of in the preceding chapter, that it seems proper a few preliminary general observations should occupy attention, before we treat of any in detail. Both series of diseases are in like manner constitutional, or residing in the blood; and the whole class agree together so nearly in cause, symptoms, and effect, that the situation of each on the various parts of the body constitutes the main distinction between them; as this circumstance does also affect the appearance and consistency of the matter produced, although in a small degree only.

What we most strenuously maintain is, that the latent cause of all tumour, inflamed glands, and spontaneous discharge of matter by skin or membrane, is entirely attributable to the actual state of blood of the individual animal. Whence we infer,
that some horses are more liable to incur contagious diseases than others, and this in a degree proportioned to the state of the blood at the time of communication; so that some might escape with impunity, whilst others meet with certain death from the self-same cause. This accounts for the greater virulence with which some horses incur glanders, for example, compared to what others suffer, which catch the disorder at the same moment of time; as was proved on a largish sort of a scale, and that pretty well known among practitioners, during the late war on the continent. The case was briefly this—A transport with cavalry horses on board, on its way to the Netherlands, met with bad weather, so that the hatches were battened down, and in this manner were part of the horses suffocated. Of those which survived, amounting to twenty-two, scarcely one escaped the glanders: but, notwithstanding, we may conclude that they infected and re-infected each other at the same moment and under precisely the same circumstances as to heat, respiration, and privations, yet the symptoms varied greatly, and some few recovered so readily as to leave great doubt whether they really had received the glanders or not, whilst others exhibited real glanders in the highest degree of virulence, and were destroyed. Between these extremes, we are informed, the remainder were variously affected: all which circumstances prove incontestably how much depended upon the previous health of each individual, the vitiation of its blood and its co-fitness or
adaptation to receive the infection. This well attested fact ought to be received as quite conclusive of the doctrine all along insisted upon in this volume, as to the actual bodily state of health, we term depravation of the humours, originating or influencing every disorder whatever. But we will adduce another authority—a veterinary writer of France, much looked up to there, who carries the principle even farther than we have adventured to push it.

With that specious ingenuity which attends all affairs of research in that country, an author named Dupuy, who also quotes the rapport of another, called Guibert, deduces the disposition to contract such disorders from the progenitors of the afflicted, or, as we should have said, from the blood or breed, and he recommends a corrective kind of regimen for brood mares and stallions; that is to say, an airy situation for the breeding stud, with pasture rather elevated, where they will have sufficient nourriture during the period of gestation, and can find occasional shelter from the weather. "By these means (says M. Dupuy) the disorder may be prevented in great measure." The disorder he here speaks of, he calls "scrophulous tubercle;" to which "all cattle whatever, bred in marshy situations with scanty allowance to the parents, are very liable." This disorder of the blood or breed, according to M. Dupuy, "predisposes the horse to contract those diseases that are known to us under the terms strangles, bastard strangles, farcy, and
defluxion from the eyes;" which latter, it will be seen, at page 346, is a corresponding symptom and never failing attendant upon the vives, as it is of all other glandular swellings about the jaws. The Frenchman thus converts a single symptom, ever attendant upon depravation of the salivary secretion or humour, into a disease!

In England, we do not talk or write of scrophula in horses, or a disposition thereto, this being a symptom of a vitiated system in carnivorous animals. For the mange in dogs, scurvical or scrophulous eruptions in mankind, and the farcy or grease in the horse, although appearing very similar to the eye of a common observer, and all originating in a depravation of humours; yet the immediate cause of each of these differs greatly, by reason of the manifest difference in the structure of the capillary vessels, or tubes that deposite the offensive matter of either kind, demand a very different treatment at our hands, and we reject the anomaly of M. Dupuy as inapplicable to horse-medicine. But when this gentleman represents the general predisposing cause as a "tuberculous or fistulous affection, that is capable of being alleviated, prevented, and in some cases cured," he brings his arguments quite within the range of our conceptions; and we cheerfully take all he subsequently adduces, as being in perfect consonance with our own doctrine respecting the predisposing cause of diseases. As to ancestry, and breeding from a good stock, in favourable situations, of which this writer
appears to entertain correct notions, we had already anticipated him by several years, as the reader may perceive at pages 75—78, which is a part of this volume that appeared in the Annals of Sporting for 1822.

THE STRANGLES.

*The Strangles,* as the name imports, is first indicated by a coughing and difficulty of swallowing, as if the animal would die of *strangulation.* It is a disorder of youth (like our hooping cough), is inherent to the nature of the animal (as is our small-pox) once only, and its virulence may be abated by inoculation, whereby we choose a favourable period for meeting the inevitable attack, after duly preparing the patient.

*Cause.*—Repletion of the *system* of life, and the deposite of coagulable lymph in the glands under the jaw; which failing to be taken up and reconveyed back again into the system by absorption, the glands become inflamed, swell, and burst, the discharge of the offensive matter being the cure. It may be considered a *critical disease,* and treated as such, by encouraging the formation of matter, and assisting nature in throwing off a something that is evidently obnoxious to the constitution. Indeed, we have never heard of any other practice; the impertinent attempts at *repression,* so frequently adopted at the request of proprietors in other cases of tumour, never having extended itself to this. *Strangles,* strictly speaking, are incident to the
young animal only—that is, from two years old, until five or near six; when the circulation has attained its fulness, and, perhaps, slight cold has first detained any portion thereof in the glands, whereby the inflammation is engendered that constitutes the disease. When these glands swell and discharge at a more mature age, the strangles must then be considered as the effect of constitutional depravation, and would as properly come under the general description of critical abscess, treated of at a former page, 312.

**Symptoms.**—A swelling commences between the upper part of the two jaw-bones, or a little lower down towards the chin, and directly underneath the tongue. A cough, a dry mouth, and the discharge of a white thick matter from the nostrils, follow; with great heat and tension of the tumours, and of all the adjacent membrane, to such a degree that the animal can scarcely swallow. The eyes, consequently, send forth the watery humour, which is deprived of its proper outlet, so that the animal nearly closes the lids: this last is an invariable symptom when it happens that the two larger glands under the ear are affected also, which frequently happens; but when these latter are disordered without the animal having the strangles, we then say he has the vives. The swelling increases and usually bursts of itself, sometimes without any medical aid whatever, and even without being perceived by any one. This last happens to colts and fillies at grass, when their wants are little
attended to, and they never fail of doing well. Consequently, it follows, that those attacks which take place in the open air are of a milder nature than those more obstinate cases we so frequently meet with among in-door cattle, which serves to prove, once more, our doctrine as to the cause of all tumours or "tuberculous affections," as M. Dupuy has it. The horses that are kept in-doors accumulate gross humours, by this mode of living on dry food and lying on soft beds, the exercise they take not being sufficient to carry of the effects of either. Enervation generally accompanies this mode of treatment; the glandular and membranous part of the system suffer relaxation; the pampered animal is not exposed to the air sufficiently to occasion that check, or slight cold, which is generally the immediate cause of strangles, and the accumulation of depraved humours proceeds, until they inflame and overcome the capacity of those organs, and the strangles then become a formidable disease.

When this is the case, the feverish symptoms run high, loss of appetite follows, with costiveness, the horse can neither drink nor eat, and the pulse increases. The tumours in these bad cases will be found to have raised nearer the jawbone than they do in a mild attack, and are longer in coming to maturity than those which begin more towards the middle. The disorder is seldom fatal; but when this does happen, the animal dies of suffocation; in which event it stands with the nose thrust out, the
nostrils distended; the breathing is then exceedingly laborious and difficult, accompanied by rattling in the throat.

Cure.—For this last mentioned extreme case, no other remedy is found than making an opening in the windpipe, through which the animal may breathe. For this spirited operation, we must refer to Mr. Field, the veterinary surgeon, who has performed it frequently, and says his practice was to cut an aperture the size of a guinea, which nature afterwards supplies in due time. With this exception, perhaps, we might be justified in saying that we have little or no business to meddle with the strangles; unless, indeed, unfavourable symptoms arise, and the previous habits of the horse, his present fleshy or gross habit of body, with the unfavourable situation of the tumours near the bone, give good reason for believing that the disease will turn out a tedious or dangerous case. And yet, we should be very loth to recommend purging or bleeding for strangles, as we have seen done with no good effect; for, although the symptoms are thereby lowered, yet the continuance of the disorder is protracted to an unmeasurable length, and we have heard of the strangles devolving into glanders by this course of proceeding—the subject of this case being a five year old, off, cart mare.

On the contrary, the disorder being constitutional, that is to say, an effort of nature to relieve itself of some noxious matters, the strength of the animal system should be sustained in a degree pro-
portioned to what it may obviously require. Therefore, horses that may be in good condition at the time of the attack, and withal highly feverish and full of corn, will only require opening medicine; whilst a brisk purgative might do harm by lessening the access of matter to the tumour, and the system would still retain a portion of the offensive cause of disease, which would break forth at a future period in some one or other of the correspondent diseases dependent on tubercular affection. In this case give the following

_Laxative Ball._

Aloes,  
Castile soap, \( \frac{1}{2} \text{ of each 3 drachms,} \)  
Ginger, 1 scruple. Mix for one dose.

If difficulty of swallowing is already perceivable, a drench would be found the more desirable form of arriving at the same end. Then give the

_Laxative Drench._

Castor oil, 6 ounces,  
Water-gruel, 1 quart,  
Epsom salts, 6 ounces. Mix.

Meantime, at the first appearance of the disorder, let the hair be clipped off close at the part affected, and a little way round, to allow of greater effect from any application that may be deemed necessary. The head being clothed, will restore as much warmth as hath hereby been abridged. Mild cases will require no more than this, probably, and the
assistance of a poultice and fomentation of marshmallows daily to the throat, to bring the swelling to a proper state for opening. This will be shown by its pointing, or becoming soft and peaked in the middle. But a premature employment of the lancet is to be avoided, for the reason before assigned, viz. to give time for the whole matter to collect; when this period arrives, the swelling will be all over soft, and yielding to pressure, unless the animal be a very thick-skinned one, with a great chuckle head. In these cases, the part should be rubbed with a stimulating liniment, and if the tumour is working its way inwards so as to threaten suffocation, blistering ointment may be applied. After each and either of these applications, the poultice is to be again put on with care; and as much of its efficacy depends upon its remaining in contact with the throat, the adjusting of it properly requires great pains and some adroitness for the thing.

Much difficulty being experienced in making serviceable bandages, a descriptive sketch of such an one as would be sure to keep on the applications is annexed. It needs no further explanation than is given in cases of sore throat at page 226, and of abscess, at page 316.

*Stimulating Liniment.*

Mustard, powdered, 1 ounce,
Liquid ammonia, 3 drachms.
Mix, and apply assiduously to the part.
The suppuration may be further promoted by steaming the head over warm water, or fumigating it with bran mashes frequently, placing the vessel that contains this, well secured, in another vessel larger than the first, into which much hotter water can be introduced, so that the vapour may rise up all round the mash, and consequently envelop the head. When the tumour is ascertained to be ripe, and not before, an opening is to be made at its most depending part, and the matter expressed gently; wash it off clean with warm water, and if the sore appear healthy, it will heal spontaneously, or with the application of a plaster of digestive ointment.
Inoculation for the strangles has been recommended above, and was partially practised. About 1802, M. La Fosse, the younger, mentioned the affair in his Manuel d'Hippiatrique, which book we translated into English the following year, and we latterly hear that two or three country practitioners in England afterwards adopted the suggestion, but they ought not to lay claim to any admiration on such an account, at least not beyond their own circles. The method was merely to scratch the inside of the nostril, and then smearing the sore with matter from the abscess of a diseased horse—it never failed. In careful hands the practice was feasible enough; but great danger would accompany this imitation of variolous inoculation, inasmuch as the matter might likewise convey a disposition to farcy or glanders.

Strangles of the gullet. Sometimes we find those symptoms of strangles reduced to one only, viz. an obstinate running at the nose, which usually lasts a long while, and occasionally ends fatally, by the animal wasting away in pulmonary consumption, as we hear from good authority, but we never witnessed such a termination of this species of strangles, which La Fosse calls "strangles of the gullet." Many people mistake this disorder for glanders, but it may be distinguished from that contagion by a rattling in the gullet, whence its French name; also, by the quality of the running, which is neither so white nor of so much consistency as the true sort, but watery and curdled. The animal
scarcely ever is troubled with a cough, and then it is very feeble; but to make up for this, exhibits frequent contractions of the larynx.

After the tumour is opened, give gentle physic, for which purpose the laxative ball recommended in page 355 will answer every desirable purpose; or you may add thereto one drachm of emetic tartar, and give another ball after an interval of one day, unless the pulse is low.

**Bastard Strangles** is a favourite term with some owners, who would soften down the real fact of their horses having the glanders, which it really is, and not strangles. But bastard or not bastard, it is always infectious, and the animal either dies of strangulation, or the disorder becomes the glanders, producing watery blackish matter at the nose. When the cough ceases, apply a

_Fumigation._

Take the leaves and root of marsh-mallows, an arm-full,

Water, 6 quarts.

Boil them, and put the whole into a nose-bag, and hang it round the head of the animal to make him inhale the steam. The bag may be made of stout cloth, but hung with the upper part quite open, to avoid suffocation. Leave the bag at the animal's nose until no more steam will arise. This will be found a very proper remedy in all cases of strangles, in the first stage of glanders, and in obstinate colds.
LAMPERS, or LAMPAS.

Cause.—As before said, page 334, lampas is occasioned by inflammation in the mouth. This is brought on by inability in the glands to secrete the saliva necessary for lubricating the gums. The parotid glands, though liable to the disorder we term vives, yet the derangement of their secretory function does not always show itself by the vives: it may continue to flow, though not in sufficient quantity to meet the increased heat of the young animal, as it grows towards maturity, and fills up the juices of its system inordinately. Idle or ill-worked young horses are most liable to lampas.

Symptoms.—A swelling of the bars of the mouth follows the rising vigour and heat of the animal; they then project beyond the surface of the upper front teeth, and interfere between them while feeding. The pain thus produced is not necessarily very great, and the animal ceases to chew of a sudden, it afterwards commences anew, with greater caution; but as the disorder becomes worse, it refuses food entirely, and starvation would be the consequence, if something did not intervene which is always sure to happen.

The cure would be effected of itself, if the horse lived in a state of nature; or, more probably, in that state he never would have contracted the pain. Over-gorging and consequent fulness of habit having occasioned the blood to flow luxuriantly towards the region of the head and throat, so that disorder
is thereby produced, the reduction of that full habit follows this compulsory abstemiousness which the afflicted animal practices much against his will, and might teach man himself a monitory lesson he is usually slow in attending to, until too late. Reducing the system is the neatest method of removing lampas, and purgatives should be employed: bran mashes, in which *an ounce of nitre* daily has been introduced, may also be given until the pulse becomes more natural. If the lampas be not lessened by these means, the projecting part is to be *seared* with a hot iron; but some people too flippantly commence operations with the searing iron, as the readiest way, and give physic afterwards. This application never fails; but if slovenly performed, it renders the horse skittish.

**SADDLE GALLS; viz. WARBLES, SITFASTS.**

The first of these partake of the nature of fistula in the withers, and are *caused* by the same means, bruise of the saddle; but being situated farther back, less scope is allowed for the spreading of the original tumour. Consequently, the smallness of the affliction renders it much less formidable, though, if suffered to suppurate, they become most troublesome sores. The means to be adopted for the cure of warbles are similar to those recommended for other tumours, viz. at *first* try to prevent the accumulation of matter by repellants, such as the embrocation prescribed at page 321; then the domestic
remedies in the next page, as verjuice, or alegar, made hot and applied by means of cloths soaked therein, and repeatedly changed. Or apply, in the same manner, the following

**Cold Lotion.**

\[
\begin{align*}
\text{White vinegar,} & \quad \{ \text{of each 3 ounces}, \\
\text{Spirits of wine,} & \quad \{ \\
\text{Super-acetate of lead,} & \quad 2 \text{ ounces}, \\
\text{Water,} & \quad 6 \text{ ounces. Mix.}
\end{align*}
\]

Should not these succeed, change your treatment, adopt the direct contrary mode, and bring the tumour forward to suppuration by means of poultices, &c. as before recommended; and finally, when ripe, open the tumour with a lancet, promote the escape of the offensive matter, and then proceed to healing the sore, as in the former cases of poll-evil and fistula in the withers.

*Sitfast* is an indurated tumour, one that has neither matter nor motion in it, and may arise from either of two causes. The first is simply a gall or bruise, which has produced no inflammation, and consequently no matter has been engendered; the second comes of an ill-cured warble, that has closed, leaving a hard insensible swelling behind. *Blistering* is the favourite remedy with most farriers, though fomentations and poultices will frequently achieve as much good in very little more time. When suppuration has taken place, the cure is to be completed by dressings of the *detersive ointment*, taking care that the sore does not heal
too fast. Should this be the case, put blue stone, powdered, upon the plaister, once or twice, or merely touch it with lunar caustic as often. Sometimes the callosity does not come off of itself, though the edges rise up; it is then to be taken away by force, separating it from the living parts with the knife. The small portion of blood that comes away does no harm, but the contrary. If, however, any one objects to the use of the knife, or doubts his skill in this operation, mercurial ointment will effect the same end, as follows:

**Ointment for Sitfast.**

Oil of turpentine, 10 ounces,
Blue ointment, 8 ounces,
Gum ammoniacum, 4 ounces;
Mix and apply to these and all hard tumours.

**GLANDERS.**

For about twenty years it was apprehended that we had arrived within a short space of finding the true cause of glanders, and that we should therefore soon ascertain the means of preventing our horses from engendering the malady, if we could not avoid their catching it, nor discover a specific remedy. But, lo! we were not yet perfectly agreed even as to the symptoms whereby to distinguish the true glanders from the false, nor either from a simple cold; neither as to that which was communicable and dangerous, compared with another affection of the glands and pituitary membrane, which was
but a temporary disease, not easily communicated, and was known to come within reach of the curative art, if taken in time. Most small proprietors, unwilling to destroy their afflicted horses, maintained that they belonged to the latter description; and in this they were frequently supported by the cupidity of practising farriers, who administered medicines and performed operations with a confidence which never could belong to any department of science—and least of all to that of medicine*, which is, alas! ever uncertain.

* Much inhumanity was shown by the country practitioners in their mode of treatment: they scraped the bone after slitting the nostril; and also seared the swelled gland with a hot iron. We owed to the elder La Fosse this operation of trepanning for glanders, who doubtless was aware that our own old writers, Gibson and Bracken, had already marked the seat and progress of this disorder. But he might have saved himself the trouble, as he concedes the moot point, by allowing when the bone is found rotten, the animal should be slain; and the old French government relaxed not its rigorous edicts against the lives of glandered horses, *suspecte de l'etre*. A late traveller applauds the practice of searing ulcers and abscesses, generally, "whereby (adds he, triumphantly) they are reduced to common scalds:" he was then speaking of the doctors in Morocco! mere Turks. The gentleman, probably, did not distinguish between *abscess* and indolent tumour, as warbles and sitfasts.

It is related by *La Fosse*, that in 1801 several regiments in Alsace and Lorraine employed the actual cautery as a cure for glandered horses. Some "applied fire to the jugular gland in three lines; others cauterised the bones of the forehead and nose; but the most ridiculous affair of all was, to see forty horses together which had fire applied round the eyelids to cure the *running*," that is so common to all glandular affections about the head! Of this running, or "defluxion from the eyes," we have already spoken, as attendant upon all diseases of the glands of the head, at pages 182, 223, 343, 348.
During this state of the question, we turned to the French veterinarians, who up to a certain period enjoyed the reputation of being superior to all Europe besides in this and a few other pursuits [war and chemistry, *videlicet*], and found one of their most respected names had arranged the boundaries and distinguishing qualities of the *two* into *three* divisions, and these into *seven kinds*. Nor was this all: after the lapse of half a century, M. *La Fosse*, the younger, who enjoyed the post of "principal farrier to the French army," and was withal a member of the *Institute*, insisted with much energy, that "glanders of the first species, the real glanders, glanders properly so called, absolutely consists of nothing more than the loss of the sense of smelling," and is "a curable disorder, *if treated early*, but incurable when confirmed." His treatment was very simple, and worthy of calm consideration, as are also the means he proposes for ascertaining by the symptoms when it is a horse is afflicted with *communicable glanders*, and *ought to be destroyed*. It is in this latter respect we reprint here the substance of *La Fosse*'s researches on this highly interesting subject; for, since none of us can offer a remedy that ought to be relied upon—unless the animal be submitted to our measures earlier than is usual—we think an useful particle may be added to the new study of *medical jurisprudence*, by showing the line of demarcation that divides health and contagion—the point at which
destruction ought to commence, by authority, or, in common humanity, to prevent the thoughtless from immolating the property of others, who are usually little proprietors, and therefore more entitled to our commiseration.

"So great has been the destruction of horses which have either really been, or reputed to be glandered, through the prejudice of ignorant persons, that it has been said, whoever can point out the distinction between the communicable disease and those which bear some affinity to it, will confer a benefit on society, and serve the cause of humanity."

What La Fosse proposes to show is, 1. "That it is easy to confound this disorder with others that resemble it, in some particulars. 2. That among the different sorts of glanders (so reputed), some are infectious, whilst there are others that are not so; and 3. That some of these are curable, and others incurable.

"There are few veterinary practitioners who do not know that strangles, strangles of the gullet, pursiveness, or asthma, and those defluxions that proceed from affections of the lungs, exhibit the same external appearance as the glanders, properly so called; consequently it is easy to be deceived on the subject, and the farrier will fail in his endeavours at a cure if he has not previously ascertained the distinguishing symptoms of the disorder. What then ought he to do in order not to be led into error,
and to ascertain with precision that species of the disorder with which the animal is affected?

"After much experience on the subject of the diseases of horses, we are convinced that it is necessary to distinguish three sorts of glanders, namely, The first sort, or merely swelling of the glands, with a pale running, which is the glanders properly so called; the second is no other than some disorder* circulating in the mass of blood; and the third may be denominated the farcy glanders. Glanders of the first kind is not infectious, except it be complicated with other disorders; but this is seldom the case, though we may daily witness horses thus attacked abandoned as incurable, or with little more humanity put to death. On the contrary, glanders of the second species is communicable, because the horse, besides running at the nose, and becoming glanderous, has likewise chancres, and these chancres appear to be the only proximate cause of contagion.

"The third species of glanders is in like manner contagious, because it not only occasions a running of the nose, but the tumefied glands and the cartilage of the nose become chancred, and certain parts of the body are likewise covered with lumps and chancres, which latter characterise the farcy

* We might have rendered this into English, as "some disorder in the functions of the lymphatic glands, which being unperformed aright, affects the circulation, or mass of the blood." This disorder is termed the humours vitiated.

R 4
glanders, the most dangerous disorder of the three, but not the most common. These two latter species of glanders are infectious, because the disease resides principally in the blood; but the glanders of the first species, although the only real glanders, the glanders simply so called, is not in anywise contagious, although it most frequently occurs.

"The second and third species are incurable, but the last only is mortal*. But, as to glanders of the first sort, it is neither incurable nor mortal. In the first place, we repeat, this disease is not mortal in any case, and a horse attacked by it is in the same situation as a man who has lost the sense of smelling; it is the loss of a sense, and the loss of a sense prevents neither the man nor the horse from fulfilling all the animal functions; for, as we daily observe men affected with ulcerated noses preserve an otherwise sound constitution, and even look jolly, so we may observe a glandered horse preserve his strength and health.

"Secondly; glanders of the first sort is incurable only when inveterately confirmed; but when taken in an early stage, its progress may be stopped with very little trouble.

"Thus we find that glanders of the first species, the real glanders, glanders simply so called, absolutely consists of nothing more than the loss of

* Why, to be sure, in a country where they executed the law upon suspicion only, where the writer himself complains, as much as he dared, that his experiments were curtailed by the strict enforcement of the law against glanders.
the sense of smelling. Its cure may be readily effected, within two or three weeks of its appearance, by frequent bleedings and fumigations. Hence may be estimated the little necessity there is for killing horses attacked by this disorder; and what important services may be rendered to society, or to a regiment, for instance, by an intelligent farrier making a proper distinction between this species of glanders and all other affections and diseases resembling it.

Cause.—The glanders is a contagious disease only when it has lasted for some time. Original glanders may be acquired by horses being shut up close together, in hot, damp stables, in swampy situations—as in the case of the twenty-two cavalry horses adduced higher up (page 348), which were confined damp, under hatches, but were variously affected, according to the predisposing cause in the constitution of each individual. Those animals were improperly condemned, because the disorder had not continued long enough to render it contagious, and they might have recovered if treated as for a simple cold.

A sudden transition from cold air to a hot stable, as well as from heat to cold, will occasion a running at the nose; or a blow there, as well as a drench clumsily administered: either of those causes being foreknown, should render us chary of pronouncing the running contagious, and thus subject the property to destruction, as proposed. Almost any running, from whatever cause proceed-
ing, or however healthy the previous state of the animal's system, causes the glands to *enlarge* and inflame; after a while, remaining uncured, they usually adhere to the bone, when alone we should pronounce the glanders confirmed. This becomes "the *second* species" of *La Fosse*, which may be communicated by contact, or by respiring the same air—in the stable; though it does not appear until eight or ten days after the infection, in the enlargement of the gland, accompanied or preceded by running. The *third* species is caused by farcy being in the system, or by inoculation, in which way the glanders has been communicated by experimentalists: the running at the nose and swelling of the glands are then symptomatic of farcy-glanders, and must be treated as such.

What inference is to be drawn from those premises, but that we should endeavour to ascertain the length of time the patient has been afflicted; whether he has received any external injury to cause it, or, has he been brought into contact with infected horses, and when? and out of the answers hereto we form the resolution of condemning the animal to solitary keeping, at the least; and set about the remedies that are likely to restore him to health. Crowded towns, posting stables, and barracks, are most subject to contain glandered horses, on account of their closeness, and the frequent succession of inmates to which they are liable; for some horses will bear it for a good number of years, the discharge almost subsiding (though the swelling of
the glands remains) upon changing to country quarters, or to a succession of regular living and regular work.

*Symptoms*.—No cough accompanies *real glanders* in any of its stages; and this, though a negative piece of information, shall be taken as a good and positive criterion that must not be neglected: a running may make its appearance, as it does at the left nostril usually, in the glanders, and the glands may adhere to the jaw-bone, as they do in real glanders, but *no cough* accompanies these symptoms of glanders. When cough supervenes, the disease may be a *catarrh*, or a *consumption*, the *asthma*, or *strangles*, but these are not contagious, unless they last a long time, and adhesion of the glands takes place: in these last mentioned disorders the discharge commonly proceeds from *both nostrils alike*; whereas, the running in *incipient* glanders is confined to the left nostril*, and the gland of one side only is then affected. Mind *that*.

As the disorder proceeds, it affects both sides alike; chancre appears all over the pituitary membrane, occasioned by the corrosive nature of the *discharge*. This assumes a different appearance as the constitution of the individual may have been more or less gross or vitiated: the appearance or quality of the discharge differs also, according to

---

* Of eight hundred cases of glanders that came under the notice of Mr. Dupuy, only one horse was affected in the right nostril.
the manner in which the disease may have been acquired; *i. e.* whether it has been *engendered* or caught by *infection*. If it come of the first-mentioned, through a depraved system, the glands are harder, often smaller, and always adhere closer, than in those cases which are derived from infection, at a time when the animal is otherwise in comparatively good health. Again, with the *infected* horse, the *matter* comes off copiously; it is curdled, and may be rubbed to powder between the fingers when dried. It subsequently hardens, and becomes chalky when submitted to acids; whereas, the animal that *engenders* the disease without receiving infection, sends forth matter that is party-coloured, less in quantity, blackish, watery, and mixed with bloody and white mucus. Finally, if the animal that receives the disorder by infection be previously in a bad state of health, those symptoms are complicated and more intense, the chancres are more numerous, the cartilages of the nose become rotten, and the bones likewise, in a shorter time: the creature seems to have combined together the evils of its own system with that of the sufferer from whom he has received it. In both cases the swelled glands are simply hard tumours without any matter in them.

In addition to the preceding tokens for discovering at an early period the true glanders from another semblable disorder, let the nostrils of the animal be examined, and the *left* or running nostril will be found of a deeper colour than usual, whilst the
other, or dry nostril, is of a paler colour than ordinary, or almost white. At this period the discharge is a white glairy fluid, and the diseased state of the sub-maxillary gland of that side is but just perceptible to the touch; but these being symptoms that belong equally to a catarrh, it is best to be guided by the varied colour of the two nostrils, remembering that in catarrh, or cold, both nostrils run.

Well worthy of remark is the fact, that when horses in a tolerable state of health first receive infection, they show mettle, and are full of freaks theretofore not experienced; as the disorder proceeds in its ravages, this mettlesomeness goes off: other acquired diseases have the same effects on all animals—the venereal, for example, on man.

A great stench accompanies the discharge in long confirmed glanders, which increases during the latter stages of the disorder; and that stable-man who has once scented it in perfection, may presently ascertain whether glandered horses have been recently kept in any stable he may examine for the purpose of detection.

**Remedies.**—Those that have been applied to the afflicted animal in this forlorn disease, are found of no avail, unless taken at an early period. As hath been said higher up, infection is not to be apprehended at first, and therefore the precaution some use to prevent its spreading, by bleeding and purging all the rest of the horses in that particular stable, is super-necessary, unless the animals require
that process in other respects; but some practitioners must be doing something, and many anxious owners will not rest satisfied unless preventive measures be undertaken.

As soon as the horse is suspected of glanders, it should be kept separate from all others, and the fumigation of marsh-mallows applied, as prescribed at page 359, repeatedly; a purgative or an alterative ball may be given, according to the state of his body, and the usual remedies as for a catarrh, continued for a week or ten days. If the disorder does not lessen in this time, but the symptoms increase in virulence, the horse should be destroyed; but unfortunately for the healthy inmates this measure is not compulsory, no statute existing upon the subject *. Besides which, disputes might arise as to the precise nature of the symptoms, and the executioner subject himself to heavy damages for his temerity. Something of this sort happened near Woburn, in Bedfordshire, early in the present century, to a lately deceased statesman. A neighbouring farmer having a horse in a state of confirmed glanders (in our opinion), persisted in keeping it in an old shed on the road-side: his obstinacy was highly provoking, and Mr. Whitbread, the

* The common law, however, is fully sufficient to prevent the improper exposure of animals afflicted with a contagious disease in horse-markets, fairs, and other assemblages of cattle. A case of this sort was adjudged at Guildhall, London, in February 1826, the facts whereof were detailed in the Annals of Sporting for the month following.
gentleman alluded to, went with his servant and shot the animal; at which the venal part of the periodical press set up a great clamour, from which none defended him, for the transaction was at variance with his public professions in the House.

Stables that have been occupied by glandered horses retain a long time the taint, and the means of communicating the disorder, which nothing will so well remove as washing with soap and sand, and scraping with sharp instruments, every part of the rack, manger, and all other parts that may have come in contact with the diseased horses. Instead of employing soap, a cheaper process is to procure concentrated chlorate of soda, a quart bottle full; mix in a pail full of water, and then with a strong brush or broom, immediately rub with great force every part of the rack, manger, and stall, and generally throughout the stable. After this wash the whole with clean water; and then pay over once more with a coat of the fresh mixture of the chlorate of soda. The same, less concentrated, by mixing a bottle of chlorate to five or six pails of the water, should be sprinkled about the stable, and the doors and windows left open to dry it, previous to re-inhabiting with uninfected horses. Lime washing is the favourite disinfecting process of most country people; it is also the most ancient, and appears to us the process best adapted to the Walls of the stable, if it be not employed upon the stalls, rack, and manger also, previous to using the chlorate of soda.
After examining the cases reported by various writers, particularly Mr. St. Bel, we have come to the conclusion, that there is no analogy between glanders and the venereal disease, but the inoculation of sound animals; and that the exhibition of mercury in any form, so much boasted by that person's successors, is utterly fallacious. One case, in which this mineral was employed with asserted success, at the Pancras College, is proved unworthy of credit, by the failure of the same medicine in every succeeding attempt. Yet did the sub-professor, Sewell, receive an accession to his salary, in consequence of his hardy assertions that he had herein discovered this mode of curing glanders!

We never had any doubt that those affections of the pituitary membrane in mankind, which causes a decided running of offensive matter in the nostrils, accompanied by swelling of the glands under the jaw, partook of the nature of glanders in horses; nor, that the disorder might be incurred by man, either by contact, by absorption, or by inoculation—if not also by inhalation: but we had still to learn that it would prove fatal, when this sheet was preparing for press, though we firmly believe that the final catastrophe might be deferred by extra generous living, as in the case of horses.—See page 104, line 23. By the Edinburgh Advertiser of May, 1829, we learn, that "Corporal Wells, of the Queen's Bays, (4th regiment of light horse) died, last week, at Cahar, of the glanders, communicated to him through a scratch in his finger
from a diseased horse.” The only question would be, “was this the real glanders,” or was the disease of such long continuance as to have devolved into putrid fever? One type of putrid fever is swelling of the glands; and as we had already stated (page 202) “is communicable to man as well as beast.” The left hand of that which now holds this pen, incurred the disease by absorption, in 1820, occasioning an enlargement on the first joints of the first and second fingers, and a swelling of the right submaxillary gland, neither of which have been reduced completely, up to June 1829.

FARCY.

Cause.—General ill state of the blood, vulgarly, but most appropriately, termed, “corruption of all the humours of the body;” and, by prevalence of the farcy-buds in the course that the veins run, all over the surface of the body, no doubt can exist that it resides in the blood. In fine, the original cause has been already defined at the head of this class of diseases, to which the reader who is fond of research would do well to turn back for a few minutes, at page 347, &c. However, infection is frequently the immediate cause, and (as observed of the glanders) the animal will be afflicted more or less severely as his constitutional health may be sound or otherwise at the time of receiving the infection. When this disease is engendered or created—which is easily supposed to have hap-
pened at first, and capable of being so produced at the present day, the blood being overcharged with offensive matters unfit for its proper purpose, it becomes stagnated at the lymphatics which follow the course of the veins (see book i. page 95), and these corrode the parts, inflame, and appear on the surface in the form of "buds." And we should feel surprise if they do not also pervade the large glands of the viscera, though we have had no opportunity of examining; such tumours on the skin of mankind have been found similarly seated on the inner surfaces, on dissection. "I feel all over as if pins were running into me," observed a patient; and so, poor fellow, he might, for on dissection I found the same sort of tumours even on the heart," observed Mr. Abernethy, in one of his lectures; and we have reason for believing that the analogy holds good regarding the horse.

We conclude, a predisposition to farcy must exist in the system, since it is only to be cured by means of correctives of the blood; and its connexion with glanders has been proved, for the one will produce the other by inoculation; and, without it, a running at the nose is likewise one of the symptoms of farcy. A certain inability to perform its office, termed "debility," that leaves the finer vessels filled with the vital fluid, which exercise might have carried off—is one main cause of farcy: and a sudden check by cold after exercise stops at once the perspiration, and the blood that would otherwise be taken up, or absorbed into the circulation, remains in those
fine vessels, as aforesaid. Hot and crowded stables relax the vessels, and indeed the whole system, when sudden exposure to the air inflicts the same evil we have just now contemplated. The reader may recollect that we referred the cause of fever to the same want of ventilation, to the same exposure to cold air, and made the remark, that the state of the animal's bodily health at the period of the attack would determine whether it should acquire this or that particular disease: the quantity and kind of cold, or chill, would also determine whether the horse should be afflicted with inflammation of a certain part of his inside, or of his whole system, which we term fever.

**Symptoms.**—Though too well known to be mistaken, we yet may describe them, as, in the first place—skin tight and dry, for want of perspiration, as just said, when some swelling is perceivable about the hind legs, and on the insides particularly. This symptom increases to an extremely large size in the course of a night, when the genial heat of the animal's system, and of the stable, appear to have matured the disease. The lymphatic vessels, and the more perfect glands, that run in the same direction as the veins, rise above the surface; and it is easy to be seen that they are sore when touched, the glands in particular, which feel hot, tight, and hard at first, similarly to the glands of the throat, as described in the glanders. A few hours confirm the exact nature of the mischief: the inflammation of those glands proceeds, they become softer, and
FARCRY. ITS THREE STAGES: LOCAL. [BOOK II.

each throws out an ichorous, unhealthy discharge. They are then termed *farcy buds*. The edges have a chancerous appearance, which it is found impossible to heal with ointments. As the disease advances, a glanderous running at the nose takes place, with swellings about the nose, lips, and all over the body nearly.

According to the constitution of the horse at the time of receiving the infection, so will the progress of the disease be rapid and disastrous, or unaccountably slow and uncertain as to the result. In this latter case the patient retains its appetite, and bears up its strength for a considerable time.

*Cure.*—Three stages of the disorder present as many methods of cure: first, when the effects are slight or partial; second, when it resolves itself into large tumours, and a more copious discharge from a smaller number of ulcers carries off the disease; third, when it is confirmed, general, and diffused over the whole system.

In the first instance, when the glands only are affected, it may be treated as a local disorder, which has not found its way completely into the animal's system; and, if appearing on one limb only, the natural inference is, that the system is indisposed to carry on the threatened evil. This happens mostly to animals in good condition, that are strong and vigorous, and of good habit of body; with such, the farcy is not brought on spontaneously, or by being engendered in the animal, but has been acquired by infection. The limb affected is
generally so to a good extent, and the corded veins scarcely visible; this happens mostly to a fore-leg (not always), and has been considered of a dropsical nature, in a slight degree, or rather lymphatic, the glands continuing their functions but imperfectly. In this case give the purgative ball, and repeat it in four days after; but should the animal be a very fleshy one, and full of condition, with full pulse, this may be preceded by bleeding to the amount of three quarts, or four.

Purgative Ball.

Aloes, 7 drachms,
Castile soap, 4 drachms,
Liquorice-powder sufficient to form the ball for one dose.

Prepare the animal with bran-mashes; let his drink be chilled, and he may be moved about, under shelter, with body clothing on that comes over the affected limb. The limb should be fomented with warm water, or the chamomile decoction, taking care to rub the part dry, and wrap it up warm. This course usually prevails against an ordinary attack of farcy, and the cure is aided when it affects the fore-leg only, by a rowel inserted under the chest. But the absorption or taking up of the disorder into the system, and carrying it off by stool, is by far the neatest manner of managing the cure; for this purpose give the following balls after the animal has been reduced by the foregoing treatment.
Alterative Balls.

Camphor,  
Emetic tartar,  
Asafetida,  
Ginger,  

\{ of each 3 drachms,  

With mucilage sufficient to form three balls. Give one of these for three successive nights; then stop one night between each dose, and go on until the disease is removed.

If these efforts to absorb the disease prove insufficient to conquer it, recourse must be had to the use of mercury, as recommended for the third or most virulent stage of the disease, which is also the most common of the three. Meantime, we come to consider of that particular kind of farcy which is the least common of all three; and this is wherein the tumours are larger than usually happens, and smaller in number. The disease then partakes very much of the nature of critical abscess (page 314), and of the strangles (page 351); both of which, the reader will perceive, are but the efforts of nature to relieve itself of an accumulation of offensive matter: and, this escaping, the cure is effected. In this second kind, or stage of farcy, nothing more is requisite than to promote suppuration, as directed in the diseases just referred to, and follow it with the physic prescribed for the strangles.

The third, most common and virulent kind of farcy, that which comes on quickest, lasts the
longest, and requires the most powerful means for its removal, is that which is spread minutely all over the body and limbs, and has penetrated the whole system. In whichever manner the animal may have acquired the disorder, we may safely presume that the mass of humours is hideously depraved, and mercury in one or other of its varied forms, is the only antidote to be relied upon for its extinction. Previously, however, the farcy buds and chancrese must be reduced to the state of common sores, by means of the actual cautery freely applied to each. When these slough off, and the sores assume a healthy appearance, less of the mercurial preparation will be required; but if these retain a livid and therefore unhealthy hue, accompanied by a poisonous discharge that ulcerates the adjacent parts, a thorough course of mercury is the only certain remedy, and this must be managed with caution.

Mercurial Ball.—No. 1.

Æthiop's mineral, 2 drachms,
Opium, 10 grains,
Liquorice-powder and mucilage to form the ball for one dose.

Give twice a day, until the patient's breath smells offensive, and then discontinue the medicine a day or two, as you should also when the animal is found to stale inordinately, or the bowels be very much disordered. But, when the bowels are slightly affected, increase the quantity of opium to 20 or 30
grains, and administer the *sedative clyster*, below mentioned.

*Mercurial Ball.—No. 2.*

Corrosive sublimate, 10 grains,  
Emetic tartar, half a drachm,  
Opium, 6 drachms.  

Mix, with liquorice-powder and mucilage sufficient to form the ball for one dose. Give as before, at night and morning.

*Feed* the patient generously during this course of strong medicine; watch its progress closely, and lessen the quantity, or discontinue it altogether a day or two when he is agitated greatly within, particularly if a kind of sickness or gurgling be discernible, and the horse is off his appetite. Let him be clothed completely. Malt mashes, occasionally sodden corn, and coarse sugar mixed with his corn, dry, are good assistants to the proper operation of mercury. That is a mistaken notion, which induced some farriers to give the edible roots, as turnips, carrots, &c. to the horse under a course of mercury; for these war with its operation, and cause that very commotion in the bowels we should most sedulously avoid. When the mercurial preparations disagree with the bowels, give clysters of water-gruel, with camphor in it, 2 drachms; this is goodly sedative. Indeed, the gruel clyster is a good assistant to the operation of any mineral prescription, by softening the parts.

In recommending the free application of the
actual cautery to the farcy buds, in the last page, we do but follow the common practice; being altogether the safest means in ordinary hands, who apply fire in many other cases, with much less reason than is done in that of farcy. Butter of antimony, or sulphate of copper, effects the same end, and has the recommendation of being used exclusively by eminent French veterinarians. What La Fosse says on this point is emphatic, and shows his opinion of the predisposing cause of farcy: “Do not apply fire in any manner to lumps produced by farcy, under an idea of stopping the disorder. The disease being in the blood, treat it accordingly, and as for the lumps, cut them off: apply blue stone, dissolved in water.” When he forefends the “idea of stopping the disorder,” doubtless in saying this he only allows that to be the true farcy, which we have considered as the third stage, or confirmed kind. But the earlier or milder stages, which would ultimately end in the third or most virulent kind, if not stopped, being occasioned by the cessation of the lymphatic function—when the attendant glands refuse to communicate with the system (the blood), cannot have yet carried the consequence of that stoppage into the blood. In making this remark, we have not overlooked what was said of the practice in Morocco at a preceding page, 364, note.

ANTICOR
Is more prevalent in France than in this country,
and is so named from its position, *anti* against, and *cor* the heart. The French words *ante-cœur* have the same meaning, and are derived from the same origin. It consists in an inflamed swelling of the breast near the heart, and the name is extended to any other swelling from this part back under the belly, even unto the sheath, which also swells: in this event anticor is decidedly dropsical.

*Cause.*—Full feeding without sufficient exercise, similarly to this whole train of disorders. Hard riding or driving, and subsequent exposure to the elements, or giving cold water to animals that are very fleshy in the forehand, as is the case with the greater part of French horses; these, combined with a vitiated state of the blood, which is then sizy, produce those extended swellings that partake somewhat of the nature of the swelled limb in grease, and yet terminate in abscess when the case is a bad one.

*Symptoms.*—An enlargement of the breast, which sometimes extends upwards to the throat, and threatens suffocation. The animal appears stiff about the neck, looks dull and drooping, refuses his food, and trembles or shivers with the inflammation, which may be felt. *Pulse* dull and uneven. By pressing two or more fingers alternately, the existence of matter, or a disposition to suppurate, may be ascertained (as in *poll-evil*) by its receding from side to side as the pressure is withdrawn. On the other hand, if the disease owes its origin to dropsy, each pressure of the finger will remain
pitted a few seconds after the finger is withdrawn. Consult "Poll-evil" in its two stages.

Cure.—As in other cases of tumour, that do not partake of critical abscess after fever, &c., this disorder admits of being repressed, readily, by the means before prescribed for similar tumour, or of being otherwise cured, as it may be allied to some disorder of the constitution. To repress the swelling, bleed the patient copiously; give purgatives and clysters; give bran mashes, and let the chill be taken off his water. Foment the throat and breast with bran-mash or marshmallows, every four or five hours; and when these have reduced the symptoms, give an

Alterative Ball.

Emetic tartar, 2 drachms,
Venice turpentine, $\frac{1}{2}$ an ounce.
Mix with liquorice-powder enough to make the ball for one dose. Give one every eight-and-forty hours. On the contrary, if the swelling depend upon dropsy, as aforesaid, let a fleam or horse-lancet be struck into the skin at four or five places distant from each other, and in the lowest or most depending part of the swelling. From these punctures a watery discharge will take place, that relieves the patient of his affliction hourly, and the issue of matter is to be promoted by keeping open the sores as directed in cases of poll-evil, &c. at page 327: again, when the swelling indicates the collection of morbid matter, let it be fomented, poulticed, and opened as
directed in cases of critical abscess, in poll-evil, fistula, &c. The whole series of these diseases are of the same nature, but differing principally as to situation, which sometimes affects the disease mainly. In this case, for example, the swelling sometimes ascends along the throat, and goes nigh to choke the patient: recourse must be had immediately to poultices, and let these be changed twice a day. The modes of bandaging may be learnt by consulting the sketches given at pages 226, 316, 336, 357.

GREASE.

Causes.—This is another of the diseases that take their rise in a tardy circulation of the blood, and consequent indisposition to take up and carry back again to the heart that which has been sent into the extremities for their nourishment and renovation. In Book I. at bottom of section 44, this process of taking up, or absorption, is spoken of, whilst the few pages that are there bestowed on the manner in which the circulation is carried on, show the importance of this function, and point out the principles that should guide us in promoting it, when aught has occurred to retard its action. When great age and consequent lethargic habits cause the blood to circulate slowly, our art can but ill supply the remedy, though the evil may certainly be alleviated by stimulants. Thus, a small portion of beans given to aged horses admirably assist the heat of the circulation of such, especially towards the heels, whilst this very species of food given to
young horses will promote humours of the *hind legs* in particular, where grease is mostly situate, and in the right hind foot oftener than in the left. That is to say, at the part of the animal that is remotest from the heart is the effect of a slow circulation most frequently recurring, and to heavy fleshy cart horses oftener than to those that are lighter and freer from meat about the heels. Defective secretion of *aqueous particles* by the *lymphatics*, and by the *kidneys*, occasions the blood to be overcharged therewith, whereupon it remains in the most dependant parts of *the system*; so much so, that the diuretic powders, or the *Alterative Ball*, mentioned six pages farther down, commonly removes slight attacks of grease.

Trimming the heels of the hair, which was intended to keep them warm in winter, is a very prolific source of *grease*. Thus, thorough-bred horses do not incur this disorder, and the chances in favour of those escaping which are produced by crosses from blood stock, is in proportion to the amount of their breeding.

A cold in the heels is caught by walking the horses through water whilst they are hot; or being put into the stable with wet feet at nights; or lying in a stable that imperfectly keeps out the wind—all conduce to that stagnation of the blood, or tardy performance of its function, that causes the animal to generate this disease. They term it *debility*, but we had better say "want of ability," or of vigour to drive on the circulation of the blood; so
that if the blood that is left behind in the fine capillary vessels be ever so good and proper for its purpose at first, yet the very circumstance of its remaining idle causes an inflammatory heat, that attracts toward itself all such congenial particles of the blood which may have been sent through the arteries to the part for the propagation of new horn, or the supply of marrow—of the nature whereof the matter of grease partakes. Indeed, we have very little doubt that the marrow is concerned in the production of grease; for, after successively examining twenty legs which were affected with grease at the time life was extinguished, the marrow was found invariably confined to the lower part only, as if it were fallen down there for want of vigour, whilst the upper part of the bone was hollow, in every instance. Healthy leg bones are always full to the top of each, and we have reason for thinking that the contrary is the case with all debilitated horses. Again, the glutinous substance that pervades the surface of the coffin bone, and to which we attribute the formation of new horny matter of the hoof, is always found scanty in greasy-heeled subjects. See observations on the foot, in Book iii.

One of those legs parted from the knee, having the skin removed, but otherwise untouched, was hung up in the yard whilst the sun was at 70 degrees (July 1825). In three or four days the grease might be seen to give a colour to the lower part of the fetlock joint, and every day the greasy
nature of the colouring was evident to touch and smell, whilst the articulation of the large pastern and sesamoid bones remained unaffected in either way. Upon breaking the bones nine months afterwards it was found that the marrow had all escaped without a puncture, i.e. through the bone.

The following ingenious suggestion we find verified by every day's observation. "Horses with one or two white feet are more liable to grease in the feet that are white than in the others; and if the proposition be true, that white feet are weak ones, we come to the same conclusion, that the want of colour having occurred through the want of vigour in the parts, then weakness and grease have the same cause."

Symptoms.—First perceptible by a swelling at the heels, mostly of the hind legs, and right oftener than left: but sometimes both heels are affected. This is occasioned by local inflammation, and is soon followed by a slight issue of greasy matter, whence the name; but it is occasionally more watery, ichorous, and offensive than greasy, a difference which will depend principally on the constitutional health of the patient. The swelling sometimes extends much higher than the fetlock joint, even towards the hough, and occasions stiffness of the limb and indisposition to move. He cannot lie down, by reason of the unbending nature of his joints, and, therefore, stands to sleep, which renders the disorder more virulent by the accession of fresh matter to the part; the skin cracks at

s 4
various places, and ulceration ensues. The hair sticks out like furze, the discharge is now darker than originally, is thin, acrid, corroding and stinking.

**Remedy.**—The *grease* is one of those disorders about which we should employ our ingenuity in *prevention* rather than the cure; and this, indeed, is the case with nearly all the diseases that depend upon constitutional defectiveness, or rather inability of some of the organs of life to perform aright the functions of nature. How these ought to act we have spoken at length in the second chapter of book the first; and pointed out the free circulation of the blood as the principal cause of health, as would also the want of a good circulation prove the harbinger of disease. Now this affection called *grease*, being produced entirely by such inactivity, it seems clear that exercise would be the best preventive of it; and the horse-keeper should also keep the heels dry after work is over, and hand-rub him a little with as much industry as he can afford, according to his wages. He should also let the hair remain on the heels of his heavy horses, and give to the large ones sufficient depth of stall and bed, so as to prevent such from throwing their long legs half way out in the stable (as often happens) upon the cold stones, of winter nights.

In slight attacks, a *Wash* made of a solution of alum, as under, will correct the *disposition to grease*, and a dose of physic set all to rights in a short time: both, however, regulated according to cir-
cu'mstances. When considering these, we should inquire into the preceding habits of the patient, as to his usual evacuations, and whether these have been stopped; for it frequently happens that grease is caused by the suspension of the pissing balls, to which many proprietors are so much addicted, that they give them without reason, or suspend the giving through the same whimsicality. In this latter case give the alterative diuretic powders, and the horse will require very little more physic. Again, if the animal require opening physic, give him the purging ball as under, and in-door exercise; but should his debility be then very great, the commotion this would occasion might reduce him too much, and therefore the alterative ball will do better, with the same attention to in-door exercise, if he can bear moving about. Sometimes, however, the heels are so cracked and chapped, that every step the animal takes only makes the matter worse; we should then assiduously apply ourselves to keeping the heels clean, with water of which the chill has been taken off, and with a brush get rid of as much of the running as possible; and, after drying it well with cloths, use the alum wash of the stronger preparation; provided always that the inflammation be not too high at the time, but which the warm water without the alum wash has a tendency to alleviate.

We will now set down the several articles just recommended above, premising this much as an apology for the numerous recipes here prescribed,
that the grease requires we should be always doing a something for the animal, either of topical application, or in devising the means of carrying off the cause of the disorder by stool, by urine, or by perspiration. For by keeping one or other of these evacuations going, we enable the animal's system to take up or absorb (as before described) the watery particles of the lymphatics, which remaining indolent in the blood constitute the disease.

_Alum Wash._—No. 1.

Alum, 2 ounces,
Blue stone, 2 drachms,
Water, 1 pint.
Mix, and wash the part two or three times a day.

_Strong Alum Wash._—No. 2.

Alum,
Sugar of lead, \[\text{of each 2 ounces}\]
Vinegar,
Water, 1 pint. Mix, and use as before.

_Strongest, or Mercurial Wash._—No. 3.

Corrosive sublimate, 2 drachms,
Muriatic acid, 4 drachms,
Water, 1 pint.
Mix, and apply to inveterate cases.

_Diuretic Alterative Powders._

Nitre, \[\text{of each 2 ounces}\]
Powdered resin, \[\text{of each 2 ounces}\]
Mix, and give in four doses, of mornings. To be continued until its effects are visible.

**Strong Purging Ball.**

Aloes, 8 drachms,
Hard soap, 3 drachms,
Ginger, 1 drachm.

Mix with mucilage sufficient to form the ball for one dose.

**Alterative Balls.**

Aloes, 6 drachms,
Hard soap, 8 drachms,
Ginger, 3 drachms.

Mix with mucilage sufficient to form the mass, and divide it into four balls. Give one every morning until the bowels are opened sufficiently. They have likewise a diuretic tendency. **Perspiration** must be promoted by the following

**Diaphoretic Ball.**

Emetic tartar, 2 drachms,
Venice turpentine, 4 drachms.

Mix well, with liquoric-powder sufficient to form the ball for one dose; and give every other night for a week or ten days, taking care to clothe the patient, or put a rug on his body at least, regulating his sweats according to the weather. Some persons do not think it too much trouble to divide the foregoing ball into two parts, and give one every night for the periods just mentioned, which would bring the whole quantity of *emetic tartar* to the same
amount in the end. Be careful to buy it genuine; and if the horse be taken care of while in his sweats, it will mainly contribute to his getting well. The patient is not to have this sweating ball whilst he has other physic in him; but it may be given alternately with the foregoing powder of nitre and resin; and is better administered thus, when it happens that the individual requires to be set a staling, and we think best to sweat him at the same time. If the medicine make his large gut to grumble, as sometimes happens, add to the ball

Opium, \( \frac{1}{2} \) a drachm,

which some do put into the prescription, whether or no. But then the opium having a tendency to bind the body, why, it counteracts our labour in this respect, and is not desirable in case the animal requires opening physic, rather than this which stills the bowels. Administer the Sedative Clyster at page 371.

Regimen.—A good generous feeding should be allowed, with a few beans for the elder patients only; and in all cases where the disorder has lasted a long while and the cure is effected with difficulty, a run at grass is greatly conducive to complete recovery; especially if the convalescent can be allowed the option of a linhay, or covered shed, lying high and dry, or the advantages of the homestead, with an allowance of corn and hay. This change of regimen is greatly assistant of absorption when the physicking has ceased, especially where the disorder
has terminated with a tedious ulceration which causes lameness, on which event he should not be exercised; but let the parts be poulticed with a turnip poultice, or it may be made of oatmeal and the grounds of stale beer, or both may be employed alternately; and then the parts, if luxuriant or thick, may be washed with a solution of blue vitriol in water, or the foregong strong wash, No. 3. Dress the cracks with the following

**Ointment.**

Oil of turpentine, 3 drachms,
Hog’s lard, 6 ounces,
Litharge water, half an ounce. Mix.

This may be varied by substituting *Venice turpentine*, for half the quantity of the *oil*. In these inveterate cases we have now under consideration, a change of medicine is desirable, if *but for the change* which it occasions in the animal’s digestive powers; for this purpose the blue pill has been given as an alterative, as well as that other preparation of mercury, the well-known *calomel*. Both act upon the kidneys, and set them in motion for the production of urine: the *calomel* chiefly effects this, by previously stimulating the liver, which again is very desirable by way of change.

**Alterative Balls.**

Calomel, 1½ drachms,
Aloes, 3 drachms,
Castile soap, 6 drachms,
Oil of juniper, 40 drops.
Mix; make into three balls and give one daily for a week; but should it gripe the animal, discontinue it; or rather add opium from half a drachm to a drachm, and give the Sedative Clyster, page 371.

SURFEIT—MANGE.

Both of these are diseases of the animal's system, and the first-mentioned proves its connexion with the second by sometimes ending in the mange. Over-feeding, or too much of it, or gross feeding, as it is the cause of these twin diseases, so are the two appellations it receives in the different stages of the attack descriptive of the cause: both are of French origin, as we apprehend; sur-fait, or over-done, being tantamount to mange in its imperfect tenses, the effect of eating too much, which has brought on the disease. The manger, as every one knows, is the place for a horse to dine at, which is again derived of manger, to eat, the noun from the verb. Neither is a surfeit an uncommon disease with reasonable man, and is alike caused by eating improperly, if not too much, and sometimes from the preparation of viands that are over-luxurious for the stomach that is to receive them, and is in fact incapable of digestion. This is a state of the stomach that is by no means uncommon, and up to a certain extent happens every day to
the full feeders of every genus of created beings. If, during this full and over-replenished state of the alimentary canal, and its then active state of lactification (or making of new blood), a sudden check be put upon the said process, by drinking cold water for example, what happens but the rapid propulsion of some part of the blood through the arteries, whilst the mouths of the offended lacteals close up for a period, and the blood, already filling the capillary vessels of the surface, becomes extremely irritable? Perspiration ceases; the lymphatics refuse to perform their office of absorption, and the blood so deposited in a due course of nature, forms innumerable small tumours under the skin, or become scabby, and throw off a dry scurf. The first has received the appropriate name of surfeit, the second is the more loathed mange, both having but one common origin. They are of the class of tubercular diseases, spoken of higher up, as partaking of glanders, are akin to grease, and to other accessions of matter on the surface, differing only as to situation, and, like the grease, require that we should promote absorption and the application of repellants.

The cause of surfeit is thus distinctly met by the means of cure. The symptoms, however, frequently announce the disorder that has taken place within but a few minutes ere they subside again, to the utter surprise of all beholders. On such occasions mischief is supposed to lie in wait, and it is generally understood that the pustules, or tumours,
only retreat from the skin to infest some more vital internal organ: but we always consider that such an evanescent attack had subsided through its own weakness, for nothing ever came of it after thus retreating spontaneously. Like surfeit in man, these tumours are attended with a pricking pain, the animal appearing restless, flinching from the touch, and looking round sharp at his legs and sides, as if he were spurred trivially. Whenever he can bring the parts to bear against the stall, the bail, or the wall, the animal will rub violently, until the hair comes off, and the skin is raw. Instead of tumours that emit a sharp, acrid, and stinking humour, like grease, a dry scurf appears, resembling scabs, and this is mange in some animals; whilst other subjects exhibit no eruption whatever, though every hair is affected in a small degree, the skin becomes dry, and he is then hide-bound.

Cure.—Surfeit is easily removed by a cooling purgative; but if the pulse be high, he should be bled also. Promote perspiration by means of the diaphoretic ball recommended at page 395, with the same precautions as are there set down. If the animal be fat, he must be reduced; give bran mashes, sodden oats, and good exercise; and should moisture be found to discharge from the skin, wash it with the

Surfeit Wash.

Blue vitriol, 1 ounce,
Camphor, half an ounce,
Spirits of wine, 2 ounces.
Mix in a quart bottle, and fill it with water. Wash previously with soapy water warm, rub dry, and apply the wash once a day, and at the same time give one of the diaphoretic balls. Let the diet be cool and opening, as scalded bran, sodden barley or oats.

THE MANGE

Sometimes succeeds an ill-cured surfeit; and is moreover an original disease, arising from beastliness, hard living, ill-usage, and the consequent depravation of the humours. It partakes of the nature of itch in man, is communicable by means of the touch, by using the same harness, clothing, &c. and probably by standing in the same stall as a diseased horse may have left.

The symptoms are stated in the preceding pages, and from its cause we may rest assured never attacks horses in condition. As in surfeit, the horse is constantly rubbing and biting himself; great patches of the coat are thus rubbed away, and ulceration frequently supplies the place. Scabs appear at the roots of the hair of mane and tail, large portions whereof fall away. When eruptions appear, they form a scurf, which peels off, and it is succeeded by fresh eruptions.

The cure is to be effected by topical applications of sulphur, and giving the same internally, as an alterative; but mercurials are mostly preferred by
our moderns: and there is not such a variety of opinions and prescriptions at this moment in practice for the most momentous diseases, as for this loathsome malady of the poor man's shed: neglect and ignorance having brought on the evil, ignorance and stupidity prescribe the cure. We subjoin a few forms of those which are in most repute, and have been found effectual: even alteration in the employment of the following remedies is frequently found beneficial, though it may not at first seem to have been for the best.

Mange Ointment.

Prepared hog's lard, 2 pounds,
Sulphur vivum, 1 pound,
White hellebore, in powder, 6 ounces.
Mix with oil of turpentine sufficient to make a soft ointment; rub the animal wherever the eruption and scurf appear, with hair cloths, or a new besom, so as to get rid of the loose filth before applying the ointment. Rub it in well every other day, and give the following

Alterative for the Mange.—No. 1.

Tartarised antimony, 1 ounce,
Muriate of quicksilver, 2 drachms,
Ginger and Anise seeds, powdered, of each 3 ounces.
Mix, with mucilage sufficient to form the mass; divide it into six balls, and give one every morning until the eruptions disappear.
Alterative for Mange.—No. 2.

Antimony, in fine powder, 8 ounces,
Grains of Paradise, 3 ounces.
Mix, and add Venice turpentine to form the mass, which divide into twelve balls. Give one daily whilst the rubbing is continued.

HIDE-BOUND.

The cause of hide-bound is commonly the same as that which produced the last-mentioned disease, viz. poverty, only that the particular animals may not both be in the same state of general health, and the more depraved would incur mange, whilst another would become simply hide-bound. This is less of an original disease than the effect of some other, and of bad digestion and consequent defective perspiration beyond all others, as may be inferred from what is said concerning the intimacy that exists between those two operations of the animal system in the second chapter of book I. at pages 78—82. The justness of this view of the cause of hide-bound was further proved by a series of dissections of this particular malady undertaken by us in May 1820. We invariably found tubercles had formed upon the mesenteric canal, on the gut, or the like kind of attack on the membrane that covers the lungs. The formation of those tumours was, no doubt, the mediate cause of hide-bound, and had been brought on by the inordinate use of
diaphoretics, the stimulating nature whereof, as is usual in all such attempts, had thus defeated itself. See pages 77, 131, 145, 150, 192, 210, in which partial hide-bound is shewn to be symptomatic of other disorders.

Horses that are so affected with internal tumours, are they which become distressed easily, though in good apparent health, upon being pushed on a journey, or at a heavy drag, particularly when the belly is distended. Thus the cause of hide-bound exists long before we can perceive it, and is the reason why we recommend the preparation of arsenic, as a tonic, previous to administering the sweating remedies. The appearance of hide-bound is frequently ascribed to the worms, bots, &c.; but in all those subjects examined by us, amounting to half a score or more, no worms were to be found of any consequence, for it would be ridiculous to talk of two or three of those stray insects occasioning such an extensive disorder, so remote from the seat of their supposed ravages. What is very well worth remarking (though such a thing is not very singular), is, that the writer who has most lustily cried out "Worms, worms!" upon every occasion of disordered skin and staring coat, has recently suggested that after all, worms are necessary to the horse's digestion; and the gentleman seems to think that these insects act upon the horse's stomach much in the same manner as pepper on the stomachs of mankind! Thus he blows hot and cold with the same breath, or rather worms and pepper with the
same pen; for, whilst the worms are so lauded in one volume of his works, the malediction remains uncorrected in the other.

Symptoms.—As the word implies, the hide or skin seems bound or glued to the bones; the animal is always very low in flesh, or we might aver that the skin adhered to the flesh. The pulse is also low, and great weakness is manifest in every step the patient takes. As the tightness is first observable at the sides of the animal’s body, before it reaches the limbs, and every hide-bound subject examined by us proves the fact, we have no hesitation in ascribing hide-bound generally to disordered digestion, which includes the negation of where-withal to digest, or starvation and hard work. Again, one of two extremes attend the bowels: they are either relaxed greatly, or much constipated—usually the former; which may be the effect of a long fit of illness from inflammation or fever, and the use of strong medicine, or much of it, in effecting a cure.

Cure the animal by the direct contrary conduct to that which brought on the illness. If its stomach be empty, as commonly happens, fill it nearly with food that is easy of digestion; if it be too full, empty it; give alterative laxatives and tonic alteratives afterwards; restore the perspiration by the diaphoretic ball recommended at page 395, and let the curry-comb and brush be assiduously applied to his coat. He may then be exercised, but not before, as it is nearly impossible, without inflicting
great pain. Besides which, forced exercise, to cause sweating, as hath been strongly recommended, would in this case only aggravate the disease; for, if the animal did sweat, it would be caused by internal pain; probably the tubercles which had formed upon the membrane would suppurate and burst, and thus confirm the disorder internally by the inflammation of the particular viscus where the disorder began.

**Alterative Laxative.**

Aloes, 9 drachms,
Hard soap, 7 drachms,
Anise seeds, powdered, 1 ounce.
Mix with mucilage sufficient to form the mass into four balls. Give, day after day, until they effect the purpose of bringing away a copious stool. Then give the *tonic alterative*, thus proportioned for a large horse, *with care*.

**Tonic.—No. 1.**

Prepared arsenic, 10 grains,
Ginger, powdered, 1 drachm,
Anise seeds, powdered, 4 drachms,
Compound powder of tragacanth, 2 drachms.
Mix with mucilage sufficient for one dose. Give daily for a week, preceded and followed by mashes, or gruel, and then give the bark, thus:

**Tonic.—No. 2.**

Cascarilla, powdered, 4 ounces,
WORMS—CAUSE HIDE-BOUND.

Ginger, 8 drachms,
Salt of tartar, 10 grains.
Mix with mucilage sufficient to form the mass into four balls; give them daily. If the preparation of arsenic in No. 1 is disliked, substitute the alterative ball at page 395 for it, and follow it up with the bark as above (No. 2.)

The following ball is calculated to improve the coat, and will be found beneficial when the animal is recovering, if given in these proportions for ten days or a fortnight.

**Alterative Balls.**

Tartarised antimony, 3 ounces,
Powdered ginger, 2 ounces,
Opium, 5 drachms.
Mix with mucilage sufficient to form the mass, to be divided into ten balls, and give one daily.

WORMS.

As remarked in a preceding page, 404, so many other disorders, external as well as internal, have been charged to the existence of worms in the stomach and intestinal canal by veterinary writers, that we find much difficulty in persuading ourselves this is at any time the precise ailment which afflicts the animal when his coat becomes staring, and his skin sticks to his ribs. Most frequently, however, that ugly appearance which denotes hide-bound, and other similar symptoms that depend upon suspended perspiration, arise from tubercular diseases
of the mesenteric canal (see page 140), and not within the gut or stomach; for the excess or the suspension of perspirable matter must alike depend upon somewhat of a more general affection than worms, that fasten on this or that part of the stomach or intestine (as we are told.) and can only influence the part they immediately occupy. Unfortunately, we know of no specific cure for worms, the remedies that are usually prescribed being of a hot, burning, and destructive nature, that are as likely to injure the intestine as the worm; it becomes our primary duty, therefore, to ascertain when the disorder be really the worms, so as to prescribe the proper remedy when we have ascertained that the fact is so. It is very easy to say a horse "has the worms," and to give him worm medicine; but much more difficult to ascertain the real fact, than to remove it when well authenticated. Our inquiries, then, should be directed towards this point as much as to any other unsettled question—the existence and quality of true glanders, for example; and yet, more fine learning has been bestowed upon the uncertain knowledge of botts, and other worms, than has attracted the attention of our veterinary writers to any other portion of their labours.

Causes.—Indigestion, and consequent stoppage of the aliment in the stomach and cæcum; which, again, may be occasioned by bad corn, musty hay, or hay made from rank grasses,—if all hay whatever does not contain the means of generating in-
sects, when used without sufficient water; also, when either substance be swallowed, as often happens, without being properly masticated, through the wearing away of the teeth, the lampers, &c. Much pampering of the appetite, by dealers and others, to produce fine coats by means of stimulants, &c. as eggs, wine, ale, bread, diapente, linseed; when the effects thereof are worn away, these leave the lacteals impaired; or offended at being deprived of a short-lived energy. The articles just enumerated form indigestible crudities, that become the appropriate nidus for generating worms in the canal, so deprived of its natural functions by artificial means. Consult again what has been said in the first book, see Index. Irregular feeding also tends to the lodgement of crudities in the caecum, or second stomach.

Symptoms.—A staring coat, with emaciation and weakness, were formerly deemed sufficient indications of the existence of worms to warrant the doctor in pouring into the animal his monstrous mixtures; for a worm case was esteemed by the old-school-men like a little salary, pro tem. Those symptoms, however, are at first rather the presage than the concomitants of worms; since they are also symptomatic of several other internal diseases, some of them producing worms in the sequel, whilst other some are found still more rapidly destructive of life than worms are, and therefore demand more immediate consideration. Slight affec-
tions of the lungs, as well as of the liver, being of long continuance, occasion partial roughness of the hair, and slight hide-bound of the integuments nearest the seat of disorder, that spreads progressively all over. The cough which accompanies severe attacks of the worms, differs from a cold in the organs of respiration; the first being more deep and cavernous, leaving a shake or vibrating heave of the flanks, whilst the former comes off with a wheeze, as if not fetched from so deep a recess.

As the disorder proceeds, and the worms may be supposed to extend their ravages, the patient's appetite is subject to extreme variation; he being sometimes ravenous after food, at others not caring to eat at all; which shows that the stomach is affected, and is frequently succeeded by vertigo, or staggers. A horse with worms that give him uneasiness in the bowels will leave off eating sometimes for two or three minutes, when a cavernous rattle may be heard coming from his inside, and he resumes his feeding. If he endeavours to kick his belly, it has been construed by the worm advocates into the pain occasioned by worms gnawing his bowels; but neither symptom is an invariable indication of worms, for he does the same when attacked by any other pain of the belly—whether colic, tight girth, injury of the sheath, &c. When the worms appear coming away spontaneously, with successive stools, no matter of which kind, it affords proof that the animal has taken grass or hay
that contains grasses of an anthelmintic property, and points out the propriety of continuing him on the same food.

A yellowish ordure appearing about the fundament something like flour of sulphur, shows the death of a good number of small worms (*ascarides*) has been occasioned by some such natural means as the preceding. Some worms come away as soon as generated in the aliment, but if no other sign of their existence is manifest, the solitary fact should occasion no uneasiness. When botts, having been detached by similar natural means, leave the stomach—where they do not always cause inconvenience, we find them adhering to the large intestines and final gut, to which they adhere and cause the animal to rub his breech against the wall or upright of the stall. Should those symptoms continue, and the generating of worms remain unchecked, the horse falls into profuse sweats on the least exertion, and when these cease, he exhibits a weak and languishing condition, scarcely notices a brisk application of the whip, his skin adheres to his ribs and flanks—*hide-bound* has commenced. Cough, more or less hectic according to his remaining strength, accompanies the patient to his end; for, as to a *cure* being practicable when hide-bound arising from such a cause has fairly laid hold of him, 'tis clean out of the question.

*Regimen.*—As the commencement of this disorder is mainly attributable to the coarseness of the animal's food, and consequent incapacity of its large
gut to expel the hardened materials, so will an entire change in the mode of feeding him do more towards effecting a cure than all the medicine we can prescribe, and all that the most liberal hand would bestow. Perhaps, it would be too much to expect that generous treatment alone should effect a cure, but we certainly have known worms voided after a few days' casual good keep, and apprehend we may attribute this coming away to the change or alteration that was so effected in the state of the patient's bowels. Hence the propriety of any change of his usual diet, as well as the advantages of alterative medicines generally. In the first place, try a run at grass, or give green food in-doors, or succulent and agreeable vegetables. If poor living has not been the original cause, we may conclude some defect in the abdominal viscera has caused obstruction, (see Index Adhesion); and the above change, in diet, with plenty of water-gruel, bran mashes, boiled potatoes, bruised corn, and the like, by lubricating the parts, may detach the worm, or at least assist the medicine, which ought to have the same tendency.

Cure.—Since the worms are not always to be killed, even by strong poisons, nor brought away by brisk purgatives, for a certainty, but are frequently discharged in a few days by an alterative regimen, reason dictates and nature beckons us to follow her course, in affording to the horse which cannot be spared from work, nor a run at grass be obtained, to adopt the means nearest thereto that lie
within the owners' reach. Laxative alterative medicines then obtrude themselves upon our notice; and in all cases are found to do good, more or less as they may be addressed to the actual seat of the disorder: in pills, if the worms lie in the intestines; in powders or liquid, if they occupy the stomach—in all forms, alternately, when we are uncertain. The various preparations of mercury, and of antimony, with Barbadoes aloe, as being more drastic in operation; also common salt, box, sulphur, savin (a vegetable poison), and sal Indicus, offer a sufficient variety for the bases of as many varied prescriptions; and variation is here most desirable, inasmuch as some kind of worms which resist the effects of one substance may be detached and hurried off by another.

Water-gruel, as it relaxes the parts, and prepares them and the worm for receiving the antidote, should precede every other remedy, particularly the mercurials; a course of which should be followed by a purgative, but not be given together, as is commonly practised. For ascarides, which usually infest the large gut, we have found great service in calomel to the amount of a drachm or more, given over night twice, followed by a purgative ball on the next morning after the second.

No. 1.—Mercurial Bolus.

Calomel, \(1\frac{1}{2}\) drachms,
Anise seed, 5 drachms.
Mix with treacle for two doses.
No. 2.—Purgative Ball.
Barbadoes aloes, 4 drachms.
Gamboge, 1½ drachms,
Prepared kali, 2 drachms,
Ginger, 1 drachm,
Oil of amber, a tea-spoon full,
Syrup of buckthorn sufficient to form the ball for one dose.

No particular care need be taken of the horse, but he should not take any gruel for the two days that the mercury is in him, as directed by James White, but give him bruised corn or other dry food with little water, the calomel not having entered the system. Neither does he require any of the exercises usually forced upon patients "in physic." Let a week elapse ere the same bolus and purge are repeated as before, when they seldom fail to bring away whatever worms he may have in him. Instead of the foregoing, some persist in the following old method, by way of laxative mercurial, which, however, we must premise, seems much too strong, notwithstanding the high character some bestow on it.

No. 3.—Laxative Alterative Balls.
Quicksilver, 1 ounce, and
Venice turpentine, 2 ounces.
These being well rubbed together in a mortar, add
Aloes in powder, 2 ounces,
Ginger, one ounce,
Mix with syrup of buckthorn, and form the compost into four balls, one to be given at intervals of five or six days. Water-gruel or a bran mash to precede each ball, as before, and give the same when the physic may be working off.

Some horses, however, cannot bear the bolus No. 1, calomel having a tendency to gripe; in that case the quantity should be divided into three balls and given on three successive nights, followed by No. 2. on the fourth morning. In like manner, if the horse be not a very strong one, the above quantity of No. 3. may be divided into six or eight balls, and given at intervals of two days each until purging is produced. Indeed, neither of these medicines should be given, least of all continued, when the animal dungs loosely. From those precautions, it is manifest that our opinions, so often expressed regarding the misuse of strong medicines, remains unaltered; and if we have been successful in impressing the reader with the same wholesome and humane truths, he will at once perceive the absolute necessity of attending to the symptoms, to assure himself that the patient really has the worms, and not some other affection of the liver, kidneys, caecum, &c, as remarked at the head of this article. Mistakes in these respects often prove fatal, or at least affect the animal's future health.

If worms actually exist, they cannot fail to come away with the foregoing course of medicine; and the patient, though a little weak at first, will come out of hand with a good appetite, brisk in his man-

415
ner, and bright as a ruby. These considerations, however, should not influence us to neglect a trial of the milder medicines, before enumerated, as containing anthelmintic properties, less powerful indeed than the above, but not therefore less likely to prove serviceable in ordinary cases. Of these, the Indian salt (sal Indicus) deserves the first consideration, though denounced as differing very little from common salt, with a small portion of sulphur, both of which are known to be goodly anthelmintic. Be its virtues what they may, the following substitute will be found to contain all the properties of the genuine salt, and may be employed when this cannot be readily procured.

No. 1.—Laxative Powders.

Sublimated sulphur, 4 ounces,
Emetic tartar, 4 drachms,
Liver of sulphur, 1 ounce,
Table salt, 8 ounces.
Mix for six doses, one to be given daily in the corn, which should be previously moistened with watergruel. As soon as the bowels are tolerably opened, desist for a week at least; but should it fail to produce this effect, continue the same, or give the following,

Laxative Balls.

Barbadoes aloes, 4 drachms,
Gamboge, 1 drachm,
Hard soap, 3 drachms.
Anise seeds powdered, 1 drachm,
Oil of cloves, 6 drops.
Mix with syrup of buckthorn enough to form the mass, and divide into two balls. Give them on two successive mornings, unless the first prove effectual. We have found these balls, without any other aid, produce worms, a few, by repeating as often as five or six times. Another preparation may be substituted for the first mentioned powder, viz.

No. 2.—Laxative Powders.
Liver of antimony, 3 ounces,
Cream of tartar, 4 ounces,
Mix for six doses, one to be given daily until the body is opened. But should not this happen, let the laxative ball just advised be given.

Savin (the leaves) pounded, and a spoonful given twice a day in the horse's oats for ten days, and then the laxative balls above, brings away slimy matter with the dung, if not worms alive.

Arsenic has been tried, to the amount of ten grains a day, for a week, but its powers are tonic only: it is, moreover, a dangerous remedy in unskilful hands. All bitters are anthelmintic and tonic; thus to wormwood, rue, and chamomile flowers, have been attributed the faculty of killing the worms; but the fact is not exactly so: those effects are produced by bracing the stomach, and restoring its tone, and thus disposing the parts to throw off the intruders.

STAGGERS, APopleXY, MEGRIMS, 
VERTIGO, FITS.

Staggers is the common or vulgar name given to all those disorders of the head which consist in vertigo or "swimming of the head." Drowsiness attending this symptom confers the distinction of sleepy staggers upon this kind of attack, whilst mad staggers is that affection of the brain which causes the animal to kick, to tumble, and plunge about: both are occasioned by diseased stomach, brought on by inflammation of that organ, or simply by the retention of a great mass of indigestible food there and in the intestines: constipation attends every species of staggers, and in some cases the hardened dung may be felt or observed by applying the senses to the proper parts. The breath is offensive, the respiration impeded, and the pulse high and sharp in mad staggers, whilst in the sleepy it is slow, heavy, and full, without vibration (see page 179). When these latter symptoms continue a long time, the blood determines towards the head, and the pulse increases, if the animal be one in good condition; and, unless bleeding and purging be employed effectually, sooner or later ends in apoplexy, or a fit of one paroxysm only, that terminates fatally. High bred cattle, stallions, and brood mares, which are pampered in their food with stimulants, frequently fall victims to this kind of attack, as do their progeny whilst under training, sometimes. In some cases the animal makes one
effort, in others it drops instantaneously; so the reader may perceive that he does not "stagger" at all: and we infer that a manifest difference exists between the two, although both arising from the same cause; for, the one we may afford some assistance to, and usually succeed in performing a cure; in case of apoplexy, the only symptom is remedyless—death. To prescribe for such an event would be utterly useless.

Under the head of "costiveness" we have already considered the origin of staggers, and prescribed the remedy, at page 199; because that is the disease, whilst staggers are but accompanying symptoms.

The megrims is an occasional attack on the sensorium or brain, in which the animal drops down as if shot, lies motionless awhile, recovers slowly, and is prepared to go and do the same thing again next day, if pushed in his work. This disorder originated in a foul stomach, in one case that came under our care, and was at first a fit of the sleepy kind, which afterwards degenerated into megrims; the morbid state of the head, it is apprehended, continued in a trivial degree, which any great exertion brought into activity. Sometimes these megrims are preceded by a short warning, when the animal rears up before it falls, or rambles like a drunkard; it then tumbles and plunges about with considerable danger to those who may collect around it. The muscles of the eye are usually affected, much in the way of horses in locked jaw, or the human...
subject in a "falling fit;" but all those symptoms disappear upon employing the proper remedies, some of them so quickly and by such means as to appear the effect of a simple mechanical operation.

The cause of staggers, and the symptoms that distinguish the one kind from the others, being thus settled, without distracting the inquirer with the needless distinctions of agriculturists or the fanciful reveries of the doctors, let us proceed to the remedies.

Remedies.—Farm horses that live much in the straw-yard, and work hard on bad hay, will sometimes stand still at once, as if struck motionless in the midst of their work, which is a sure sign that some great leading function has been suspended for the moment by reason of the great exertion. The driver has nothing more to do in this case than to let the tired creature rest for the space of a minute or two, and than proceed in his work a little more leisurely.

In all ordinary cases of staggers, simply opening the bowels will effect a cure, nine times out of ten; and when the animal shows symptoms of a disordered stomach, the coming disorder may be warded off by a dose of physic. In violent attacks, let a clyster be first employed, of warm water, in which common salt has been dissolved, and the hardened dung brought away by manual assistance—as more fully detailed elsewhere—see the mode of doing this effectually, at page 199. We have found violent cases of staggers cease by this remedy alone,
and the cure was completed with a purgative ball, as prescribed at page 185.

The fits that constitute megrim, or the more genuine staggers, will require the flaim; and let the quantity of blood taken be commensurate with the violence of the animal, his bulk and fleshiness. From four to six quarts will thus reduce his powers, and aided by the back-raking and purgative just recommended, a cure is soon effected.

**LOCKED JAW**

Is rather the effect of other diseases, of the acute kind, than an original attack, and is symptomatic of approaching death. A prick in the foot and docking the tail, are fruitful causes of locked jaw. Hot weather is most conducive to this manner of dissolution, which is brought about by great excitation of the nerves, accompanied by imperfect digestion. The remedy would of course be found in restoring the tone of the former, and opening the main outlet of nature. We have seen a case of locked jaw proceeding from inflammation of the intestines, of a very aggravated nature.

*Symptoms.*—The case alluded to was that of an old horse, from twelve to fourteen years of age, just off from hard work, which seemed to have lived badly and suffered severely the ills of a protracted life. Date, May 14, 1820, when the weather was prematurely hot. As usual, it began by the animal thrusting out its nose and eating with some diffi-
culty, which increased as the stiffness of the neck became worse. The ears stuck up, whilst the sufferer could scarcely move a foot, and this with the greatest pain. Thus it is, every hour the malady is found to extend itself towards the more vital parts, until reaching the heart, life is then extinguished. The brain appears to be affected at the very earliest period of the attack, when the animal evinces unusual apprehension, and will neigh and prick up its ears at the approach of any one, as the last effort of nature to obtain the notice of man. The pulse is then increased to about 50; but in the future stages of the disorder it falls again below 40, and lower still until its final extinction.

In a few hours the balls of the eyes of the animal just alluded to were turned back, showing the nerve which retained the ball in position in a distressing manner; he appeared to suffer much pain, respiration had ceased, the abdomen was drawn together, and immediate dissolution might be expected momentarily. When the subject was opened, we were struck with the inflamed state of the mesentery, and all the lacteals assumed a bloody appearance. Previously to this catastrophe, we hit the animal hard on the forehead with the fist, once; the blow shook his whole frame, which before was as stiff as if made of wood; its eyes immediately returned full one-half way back again towards the proper situation, and we plainly saw that its jaws, which had been knit together, seemed to relax somewhat, and the rigidity of the neck gave way.
Remedies have been prescribed, and Mr. Wilkinson of Newcastle reports several cases of successful practice upon young horses which had acquired locked jaw by being either nicked, or docked, or pricked in shoeing. The chief obstacle to the administering of any medicine being the closeness of the teeth, which defies the introduction of a horn, it may not be amiss to observe, that profiting by the foregoing experiment, we have in several cases caused a little relaxation in this respect, by placing a piece of wood upon the forehead and striking a smart blow upon it with another piece or a small mallet. Some substance is then to be placed between the teeth to prevent their return to the original closeness, whereby the remedies recommended by Mr. Wilkinson may be employed with much prospect of success, for he only failed in four cases in which the jaws were immovable by any means which he then knew of; and as he has treated this particular subject more happily than any veterinarian of our time, we cannot do better than follow the example of copying his account of a well-marked case successfully treated.

When called in, he observes, "I found the symptoms were a spasmodic affection of the muscles of the jaws, head, neck, back, hinder extremities, and abdomen, which occasioned them to become rigidly contracted; the pulse was about fifty, with some irregularity, the breathing a little quickened, the jaws were considerably shut, but not so close but medicine might be administered as a drench with a
small horn; the appetite not diminished, but she could not masticate hay; the head somewhat raised, and on elevating it a little more, the haws covered great part of the ball of the eye, the nose was thrown out from the chest, the nostrils expanded, the ears erect or perched up, a great stiffness of the neck and back, the tail a little elevated, and, upon a little fatigue, a shaking of it, and straddling of the hinder extremities: the animal was very costive, and the urine was somewhat diminished. The mare had been shoed about three weeks before, and the farrier had driven a nail into the sensible part of the foot while shoeing her. The lameness thus produced was soon removed, and the disease came on after performing a journey; that is about three weeks after the injury in the foot had been inflicted. Two quarts of blood were taken off; a purgative drench and an emollient clyster were given; considerable friction was used over the muscles of the jaws, head, neck, and back, particularly where they were found most rigid; a stimulating liniment of turpentine, hartshorn, mustard and oil, was well rubbed over those parts, which were afterwards covered with sheep-skins, as recently taken off the sheep as they could be procured, which soon brought on sensible perspiration. The diet was principally thin bran-mashies and oatmeal-gruel, of which she frequently took a little. Next day, pulse the same, breathing a little quicker, jaws not more locked; a constant perspiration had been kept up by the sheep-skins; the purgative drench not ope-
rating, another clyster was administered, which promoted its action: the liniment was repeated. Next day (the ninth), symptoms nearly the same, perspiration copious: the purging having subsided, the anti-spasmodic medicine, composed of opium, camphor, and asafoetida, was given with a small horn morning and evening, and a similar mixture, with the addition of three pints of a decoction of rue, was administered as a clyster, morning and evening. The drench and clysters were repeated morning and evening till the 14th day; and during this, the quantity of opium, viz. 1 drachm, was increased or diminished according to the violence of the spasms, which at times were very severe. It was always administered in such a manner as to have its effects constantly in the system, without producing restlessness; during this time, there was also a most copious perspiration going on under the sheep-skins. The bowels becoming costive again *, another purgative drench and an emollient clyster were administered. On the 15th, the drench not operating, a clyster was given, which produced the desired effect. Pulse and breathing a little hurried and irregular, jaws not more locked, still perspires under the sheep-skins, appetite good, but cannot masticate hay. 16th, Pulse more regular, breathing more calm, perspires freely under the skins: the purging having subsided, the opium,

* In consequence of the repeated doses of opiates, an effect that may be avoided by omitting the camphor in the drench, and dissolving it in the clyster.
&c. were administered as before, and continued until the 21st, when another purgative drench and emollient clyster were given. The jaws were now more open, and the mare could masticate hay: the muscles of the head, neck, back, and hinder extremities, became considerably relaxed, and on raising the head, the haws did not cover much of the eye. On the 23d day, the purging having subsided, the anti-spasmodic medicine was again employed until the 10th of April, when another purge was administered. On the 12th, the purging subsided; the anti-spasmodic medicine was again used a few days longer, when she was completely cured of the complaint. After this, tonics were given, which, with a nourishing diet and suitable exercise, soon restored the tone of the muscles, and the animal became as useful as ever."

Of the twenty-four cases described, nine came on after docking or cutting off the tail, from ten days to a month after the operation. In such cases, the tail was fomented with warm water, and the sore dressed with detersive ointment. It should be remarked, that in all the successful cases the jaws were not so completely closed but medicine could be given with a small horn, or introduced as a bolus, by means of a cane. In some instances, there appears to have been considerable difficulty in giving medicine at first, but by persevering carefully, both medicine and food were introduced in sufficient quantity. With respect to cold application, Mr. Wilkinson says, he has only tried it once, when the
whole of a mare's body affected with locked jaw, except the nostrils, was immersed in snow for some time, without producing any relaxation of the muscles: on the contrary, the symptoms afterwards gradually increased, and she died on the third day. In four cases that terminated fatally, the jaws were so completely closed, that neither food nor medicine could be given by the mouth. On examining these horses after death, there was some degree of inflammation in the lungs, stomach, and bowels. It was generally found on opening the spinal canal, that the membrane covering the marrow exhibited a very inflamed appearance, and the marrow itself was tinged of a still darker colour, whilst the membranes of the brain exhibited some marks of inflammation.

HYDROPHOBIA.

No notice whatever would have been taken of this dreadful malady, but for some additions to the stock of information already before the public as to the means of discriminating the true from the false rabies, with which we are furnished from authentic sources. A disease confessedly incurable requires no more to be said of it; but this having been, at one time or other, the case with several other subjects treated of in this volume, we cannot, consistently, pass it by in silence. Even the names of authors who have written on canine madness would be serviceable to such of our readers as may be
desirous of extending farther their inquiries concerning this melancholy and appalling disease. Preceding authors have all confined their information to the dog itself, with mere casual notices of his attacks upon other animals, and on man. Their researches extended not to the horse, or but trivially so. But, inasmuch as the symptoms of madness discoverable in dogs so affected are good to be known to those who would keep their horses out of danger, we thus feel further inducements to bestow a page or two on the distinguishing character of the true symptoms, and add a hint or two as to prevention, since cure is nearly hopeless at present.

Causes.—The bite of a rabid animal—universally of the dog, and in every case that we hear of, on the lip of the horse. The bull-dog, the lurcher, the mongrel, the Danish dog, and the shepherd dog, are the kinds most disposed to run at horses, especially when so affected (the first-mentioned, on other occasions, usually fighting at the throat) jumping repeatedly at the horse until they get hold, and the two first pertinaciously holding fast a long time, even until killed off', as we hear and believe. This will happen mostly with horses tight-reined, or which we bear up in harness, whilst those having the head loose will rear and paw off the offender, or being at large, evade or trample upon him; but however slight the bite, the mischief is already committed, so that avoidance by flight is the only preventive of an irremediable evil, unless we are pre-
pared to shoot the caitiff, or to run him through. We hear the free use of horse-flesh for keeping dogs in England charged as one main cause for engendering rabies, or at least quarrelsomeness; add to this, the denial of water to which some of them are subjected at a season when dilution is most required—"what time the dog-star reigns," and we think the suggestion worthy of being received as one particle in the science of medical jurisprudence. Certain we are, that this appalling disorder is comparatively small in other parts of the world, where horse-flesh is less plentiful, or water, the antidote, is found in abundance; at Lisbon, for example, where dogs perform the office of scavengers, and are supplied with water by individual housekeepers. Our own towns, too, in which water is easily obtained, are much seldomer subject to epidemic visitations of rabies than others more arid, yet lying open to an access of carrion in abundance. Dogs invariably take water with much eagerness in every stage of the disorder, so far as we have seen, or heard of orally; some printed accounts differ, but we rely little on the periodical scraps that are necessarily brought out with too much haste to be accurate. Man dreads it; but when he can get it down, which has been done within a day or two of his dissolution, he finds the raging heat of his stomach alleviated by the effort.

Symptoms.—In the dog, the approach of rabies may be known by a marked deviation from the general habits of his kind, amounting to dislike of former
friends, a symptom which ought to be particularly regarded. *Rabid dogs* have been seen to eat their own excrement, and lap their own urine, besides other marks of depraved appetite; though at this early stage of the complaint they are less likely to attack a horse than to resent an affront, or be guilty of treachery towards friends. But as the disorder increases, he shows an inordinate desire to gnaw any substance whatever, and evinces augmented antipathy to cats. Even the dog called *Danish*, though mostly kept with, and very fond of horses, would, as soon as affected, be the most likely to snap at his old companions' noses. As the malady increases, his eyes become inflamed, and are affected with a blearing from the lids. He howls horridly when the throat is inflamed at the *larynx*, or part whence the *voice* (barking) proceeds; the which sound, whoever has once heard, he can never afterwards forget or mistake, unless he himself be bit, or become deaf. The confirmedly *mad dog* now usually sits upon his rump to howl his obstructed bark, through very pain from apparent intestinal inflammation. If suffered to range about as the last stages approach, he seems bewildered and devoid of sight, and should be either avoided or attacked with clubs and other weapons to extirpation: *feeble* opposition is obviously dangerous.

*The symptoms* of hydrophobia coming on upon the horse are direct and positive; *blood* on the lip, and other marks of violence, convey the first intelligence that the mischief has been inflicted; for
neither horses, sheep, nor neat cattle incur rabies without inoculation. We are further told, by M. Husart, that they do not possess the power of communicating the disease by bite to other animals, even though labouring under the highest degree of hydrophobia at the time; a fact we do not further vouch for, but which, when proven by well-marked cases, would go far towards inspiring confidence and certainty in applying any of the alleged remedies. What man is bold enough to administer a ball, for example, whose own life is at stake, ingloriously, by the feat? Increased pulsation, inflamed throat, and evident thickening of the membrane that lines it; soon after, the stomach being also inflamed, rejects food, or the patient is at least indifferent to it, which may occur about the eighteenth day after the inoculation; four or five earlier if the animal be in good condition, so still sooner if high fed and full of blood. Shortly after, i.e. from five to eight days, the bitten parts enlarge, and difficulty of swallowing, evidently prove that the disorder is making progress; the patient rubs the part against the manger, stall, or wall, increasing in vehemence from the twentieth or twenty-third day. He does not drink water freely, as usual, though this is by no means a certain criterion, for his power of swallowing is already imperfect: he does not flinch from water when sprinkled over his face, but will ever drink to the amount of a pailful, when occasionally he can find free passage for it, and the whim may be said to seize him. Some rabid horses
will take to water, and one in a very high state of excitement was known to have run into a river. Suppression of urine next proves that the inflammation has reached the region of the kidneys, which is effected by way of the stomach; perspiration and excessive exacerbation ensue, with inflammation of the parts of generation, accompanied by contraction in the male—yet a gelding was found to have protruded its sheath; and staled with much pain to the amount of half a pint, about the twenty-fourth day.

Weakness of the back and loins sometimes is observable at any period of the disease; some quadrupeds being thus attacked, and falling down mad without previous indication of rabies.

The eyes glassy, fiery or red—loss of vision; tongue sometimes shoved out, and then gnashing of the teeth. The raging symptoms increase from the twenty-second or twenty-fourth day to the twenty-eighth or thirtieth day after being bitten, when the animal will beat itself to death, unless the owner more humanely puts it out of pain with a musket: for 'tis dangerous to approach within reach: the interposition of a strong gate across the stable, and the application of a beast rope well fastened, are good preventives of accident during this final operation, or a cart that will bear some kicking might be backed upon him.

Regimen.—None will afford any permanent relief, though it has been usual to place before it water as a test of its madness—though now known
to be a fallacious one in any state of the disorder with any animal whatever. All rabid horses continue to feed up to a certain period—until the stomach is attacked—and some eat voraciously in the intervals of the fits; and drink too, but no good can be expected from either, unless made the vehicles for the introduction of some nostrum. If a cure be attempted, certainly nutritious food, easy of digestion, and cooling, must assist it. The stomach being very much inflamed in this disorder, points out the propriety of bran mashes, marshmallows, and of water gruel, given cold, which will afford the means of alleviating the anguish of that organ, to the coats whereof the last food taken by the expiring patient has been found to adhere after death; that is to say, the fibrous coat of the stomach of the subject alluded to identified itself with the food so intimately, that it stripped off, whilst the insensible coat still adhered.

Remedy.—Every possible remedy, some of them of opposite tendency, has been tried on the dog, and on man. Sea-bathing, the Ormskirk medicine, copious bleeding, excision of the part, the actual cautery, and cupping the parts, have been each employed—successfully, we are told; but no reliance can be placed on either, since they oftener fail; though there is no reason why the horse should not undergo bleeding and cutting off the laceration as soon after the accident as possible. When we consider that the part bitten is ever observed to enlarge previous to the horse showing
other signs of confirmed hydrophobia, it seems clear that the cutting off the immediate cause of incipient rabies should press itself upon our notice as the most efficacious means of warding off the disease. Six months is no unusual time for dogs to conceal rabid infection, a quarrelsome disposition being for a long time the only indication perceptible; but the horse seldom goes beyond the twentieth day in developing all the symptoms before enumerated; which shows that the peculiarly rapid circulation of the blood, noticed elsewhere (page 171) as the harbinger of inflammatory complaints of every kind in the horse, naturally demands early and copious bleeding as a good accessory remedy for this particular one. In this case alone we should not be solely guided as to the quantity of blood proper to be taken by the quickness of the pulse, or actual inflammatory indication, but its fulness, and habit of the patient’s body: empty his body subsequently, as directed in cases of fever, with a brisk purgative, as follows:

**Purgative Ball.**

Aloes, 7 drachms,  
Calomel, half a drachm,  
Hard soap, 3 drachms,  
Oil of caraways, 12 drops.

Mix with mucilage sufficient for one dose. If the animal seem not otherwise to require purging physic, omit the calomel, and omit it also if the bleeding
has been trivial on account of the previous low state of the animal's system.

The application of the plant *Scutelleria laterifolia* is reported from North America to have succeeded in several cases; but the symptoms do not accompany the report made to us, and we rest in doubt as to its efficacy. However, let it be tried. So we say of "any mineral acid," which a certain medical gentleman recommends may be applied—a few drops on tow to the wound whilst fresh. This may be tried in the form of *oxygenated muriatic acid*, which has the property of being destructively detersive; it decomposes the virus, and acts as a styptic. *Salt water* bathing has been employed upon a large scale, and has been loudly commended; then, let common salt be also tried to the amount of two or three ounces a day mixed with the patient's corn. It is but fair to add, that sea-bathing failed to effect any good, when tried upon the *canine* under the best auspices. The king's stag-hounds, in 1823, being more than suspected of *rabies*, were take to Brighton, and the ablution was well performed under the directions of Mr. Sharpe, the huntsman, but to no good effect; they were all destroyed. *Dr. Fayerman*, of Norwich, published a case in the spring of 1825, of the cure of hydrophobia in a man of forty two years, by giving him *superacetate of lead* (Goulard's extract) in doses of from fifty to ten drops on lumps of sugar. He also bled the patient, who was at one time *raging mad*. Strong soap-boilers' *lye*, or solution
of potash, in either of its varieties, has been used frequently as efficaciously detersive of the *virus* left by the bite or bites inflicted by a rabid enemy; besides which, the seat of all the wounds may thus be ascertained, as they usually lie concealed by the hair; and thus, if excision be deemed necessary, every injured part may be similarly treated: let the eyes be guarded against the lye, and the wounds should be assiduously washed and quickly pressed. An eschar forms and completes the cure. The once *celebrated* "Ormskirk Medicine" is unworthy of reliance.

The subject of *canine* madness has been well handled by Mr. Gillman, in his "Dissertation on the Bite of Rabid Animals," 8vo.—Mr. Daniel, in his "Rural Sports," has made some good, sensible, practical observations on this subject. Mr. Thomas, in his "Shooter's Guide," is more pithy than communicative; he recommends immediate death being visited upon the victims of the disease; a very effectual mode of *preventing* communication, truly; but he seems not aware that premature judgments would be very likely to consign to death many good animals afflicted with *other disorders* than *rabies*. Subsequently, Mr. Johnson, in his "Shooter's Companion," has printed some interesting details of occurrences within his own proper sphere. Dr. John Pinckard's "Cases of *persons* who have fallen victims to *the bite*" are well marked. But the labours of none are so much in point, as regards the *horse*, as the researches of our friend, Mr. John
Surr, Surgeon, communicated to us, subsequently to 1810; in which year he published the result of his dissection of several horses which had died of hydrophobia, partly under his own inspection*. The substance of all our friend's observations is embodied in the foregoing pages. A writer, who adopts the signature of H. C. in addressing the publisher of the *Annals of Sporting* †, has communicated much practical information on the subject of *canine madness*, that is well worthy the perusal of all persons interested in this order of created beings.

* Those papers appeared in the "Medical and Physical Journal," No. 131, and several successive numbers; Mr. Surr being accompanied on one occasion by Dr. Adams and Mr. Pettigrew. The subsequent decease of Mr. Surr ought to call forth the sincere acknowledgments of his private worth, in addition to this tribute to his professional industry; but this course would be little consonant with the wishes of the majority of our readers, it is presumed, and we reluctantly relinquish that design.

† First in No. 34, p. 226; in No. 35, p. 259, No. 40, p. 224, and No. 44, p. 77. These papers should be read by every one having aught to do with dog or horse; indeed much real good might be done by printing a cheap edition by "the Tract Society," for distribution. They should be preceded by the very nervous appeal that called them forth; which appeared in the *Annals*, No. 33, p. 191, from the pen of our friend Jon Bee, and also gave the impulse to "T." on the same subject in No. 44, p. 75. See also No. 7, pages 4 to 9.
BOOK III.

CONCERNING THE LEG AND FOOT OF THE HORSE; OR
SHOEING SMITH'S GUIDE.

CHAPTER I.

Structure and Physiology of the Foot; Mode of studying it advantageously.

Certain disorders of the foot owe their origin to bad structure of the limb, and the manner it is attached to the body, which influences the tread, or bearing, that the foot has upon a plane surfaced ground; others arise from accident or hard work, and a good number from the errors shoeing-smiths fall into when they neglect to adapt their work to the circumstances peculiar to each kind of horse. Furthermore, almost every individual horse has its peculiar tread, and the scientific workman should place himself in a situation to ascertain whether this be owing to such original defectiveness, or to the evil accumulations of age and hard usage: he must not pretend to counteract, but to follow the first mentioned; the second he may endeavour to correct, to amend, and prevent its evil consequences. In
order to effect these objects, he should study the true form and structure of well attached limbs, learn the uses of each bone, ligament, and tendon, and ascertain how it happens that deviations from symmetry in the limb always affect the sole of the foot, sooner or later. For he may rest assured, that at the sole the horn is prepared in its liquid form which afterwards ascends to the coronet, as we shall show presently; and that hence arise many of the evils of mis-shapen hoofs, of ill-secreted horn (whether brittle or soft), and the occurrence of several other diseases there that frequently depend upon constitutional ill-health, but which never would appear on the foot at all were it not for such contractions of the horn, which further obstructs the action of the sensible part of the foot; whilst again, this obstructed function also occasions a defective supply of horn, and consequently hoof inadequate to its purposes, as well as distorted. In those dozen lines are exposed the cause of nine tenths of all foot-lameness whatever.

But so much space has been already occupied in the description of the shape and attachment of the legs, that it might properly be considered a waste of time to enter into new details to the same purpose. The reader will therefore turn back to the early sections of the first book (page 25, &c.) and he will readily perceive in what manner an originally defective limb, or the ill-adaptation of the parts to each other, or its awkward attachment to the body, affects the tread in earliest life, may become the harbinger of

u 4
one or other of the many diseases of the foot, which we come shortly to take into consideration. He will know, also, that besides this error of birth, there are others of mismanagement: as, the employment of horses in work that is beyond their powers, or of that kind for which nature never designed them; either of which is as likely to bring on distortion of the foot, and its train of disorders, as any accident of birth. Natural defects go much farther than shape or make, and the distinction between these and the inflicted, or acquired, may be aptly illustrated by the fact, that white-legged horses, whatever be their shape, are more disposed to contract "grease" than those of any other colour. This is, therefore, a natural predisposition to that disease; whilst the animal which is suffered to contract the "grease" entirely through mismanagement suffers an infliction as much as another, which, being put upon hard services, throws out splents, spavin, curb, &c. in consequence.

Furthermore, the shoeing-smith who should inform himself of the primary causes of badly-formed feet would carry on his business with the greatest emolument to himself, and with most satisfaction to his employers; for he would adapt his shoes to the natural defects, whilst the acquired ones he would amend by degrees, until he could control the horses' heels to a healthy shape, and thus promote the regeneration of healthy horn. He should also accustom himself to reflect on the various breeds of horses that are brought under his care, their limbs
and hoofs, produced in certain situations, climates, or countries, as we hear them denominated, each of which requires some peculiar contrivance or adaptation. Thus, horses bred in swampy situations, have long flabby limbs and large flat hoofs, to say nothing more of their long washy carcasses, that predispose them to contract certain ills that fall into the foot, which come shortly to be enumerated. All those "countries" where ague prevails among mankind are unfit for breeding good horses, as is proved by the thick spongy heel and soft hoof. Brittle hoof is produced by a hot, sandy breeding country, which affects the heat and dryness of the animal's constitution. But, to whichever extreme the individual belongs that may come under consideration, mis-shapen hoof is visible from the earliest years. This increases as the animal is worked, and disease of one description or another follows, which requires the care of the shoeing-smith to modify, or of the doctor to cure.

In the anatomical treatise that occupies the first chapter in this volume, the reader will observe (at page 44) how strenuously we insisted on the proper shape or elevation of the hoof; and he will not overlook the great service our shoeing-smith, or ferrier proper, may derive from duly considering this shape and external form, and of adapting his shoe to each deviation from the true form. For that attendant upon and assistant to nature, who is neglectful of her deviations, or ignorant of the causes which produce them, is ill calculated for his
Duty of studying deformities; and

office, whether that be ferrier or doctor; in fact, he is ever the most prizable workman of either class who is best acquainted with those deviations, accidents, or errors that, for the most part, are inflicted we know not how. The boot and shoe maker, for example, who can best suit the bumble-footed man, is a more ingenious mechanic than he who is wholly employed in making his cordovans for perfect-footed persons only. But then, the "shoe-maker" of either genus should not be ignorant of well-turned feet, and the symmetry of the horse's foot should form an especial part in the education of an intelligent shoeing-smith; else, how is he to work for the preservation of the proper shape, or its restoration when time and circumstances may have effected those alterations we deplore, and strive to amend if we cannot fully restore them?

Let him examine nature itself in its fastnesses; let him investigate the minute parts that constitute the whole foot, to which his operations are calculated to afford support, or to effect alterations in its form. To aid him in his inquiries, hereto is annexed the section of a foot of nearly perfect shape, published some time before these sheets, in order to meet and correct the blunders intelligent shoeing-smiths were every day led into by relying upon the misrepresentation of the subject contained in certain authoritative publications of the present day. As an antidote to all mistakes on this interesting topic, we strenuously recommend every one who has occasion to meddle with horses' feet, as owner,
groom, or shoeing-smith, to obtain a fresh hoof of a horse which has died in comparative health, and having softened it in warm water, proceed to make a section thereof, in the same manner as is here done.

**FIG. 1.—SECTION OF THE FOOT.**

This portrait of a section of the healthy hoof was taken from a freshly severed foot of a five-year old horse, recently killed in full health. This latter remark veterinary readers will know how to appreciate, when comparing this with their own preparations, which may have been derived (as generally happens) from the anatomy of diseased subjects, after the juice which should have supplied fresh secretory matter has been long turned aside, or converted to increase deformity. A fact that is further illustrated at page 451.

To the general observer, the foot of a horse inclosed in its hoof would, indeed, seem like a
corpse shut up in its coffin*: and there is, certainly, no mode of arriving at a knowledge how these act upon, and with, each other, but by dissecting the hoof. By this means the whole arcana of its construction are laid open, but in no manner so intelligibly as by the section straight up and down from the toe up to the coronet, and throughout between the clefts of the frog and heel. This being done, the vessels which supply the juices for renovating the wear and tear of the whole exterior are plainly bared to the view: the ligaments, bones, and tendons, show their means and manner of action; and, above all, the back sinew laid flat behind the smaller pastern-bone, and quite so at passing underneath the navicula, and at its insertion in the bottom of the coffin-bone; where its structure being altered, it receives the designation of "the sensible sole," partaking of the shape of the horny sole, which we see upon turning up the foot.

On entering the hoof of the fore foot, the back sinew acquires the term tendo palmaris, among the learned, at the hinder leg it is described as tendo plantaris, and is here at its superior part the seat of a disorder we call string-halt; but within the hoof, when fever has diminished the secretion of horny matter, and the internal parts of the foot adhere together, both tendons are affected with the general rigidity, which some persons pretend to distinguish as "the navicular disease," sup-

* Writers of the last century were wont to give this term "coffin" to the horn we now describe as the wall.
posing the shuttle-bone (navicula) only is affected; others term it "dislocation of the coffin-joint," "a disorder of the lamina," and other fanciful names; whereas, whenever the secretion that supplies the elastic process and lubricates those several parts, falls short, all suffer together, nearly, by growing into one jointless lump of bone.

At a on the coffin-bone, the general porosity thereof is much greater than at any other part, being the avenue or receptacle for the blood which is diffused throughout it, except on the surface, or border, (at bbb). The shape of this bone at the toe (l) is worthy of note, as being that which is best calculated to give firmness of tread, fitting with the greatest nicety to the shape of the hoof; or rather, perhaps, we should say, that the shape of the hoof of a healthy animal should ever partake of that which we have before us, and is evidently instructive to the shoeing-smith in his final raspings, to keep clear of the coffin-bone, whilst 'tis of its proper shape*.

* Is it not strange! but no less true is it, that since the foregoing 'section and description' was published—in the Annals of Sporting, for June, 1825, Mr. Goodwin, the "late veterinary surgeon to his majesty," retains the following passage in his "system of shoeing," page 181, viz. "Mr. Bracy Clark remarks, that the French method of shoeing is more conformable to the natural form of the foot, and that it harmonizes with the shape of the coffin-bone, which he illustrates by stating [what is not true] that if a coffin-bone be placed flat on a table, it will be seen that there is a considerable space between the toe and the table. This is certainly correct," adds Mr. Goodwin, complacently aiding the assertion of his preceptor; but it is, nevertheless, a—sad blunder; as any one not blind may perceive by a single glance at the foregoing cut. The thing is palpable, and we conclude that friend Bracy having fallen into error, inadvertently,
Even when we find it necessary to bleed at the toe, or to keep it very short in order to strengthen the wall, the horse must have rest, or ruin ensues.

Between the hoof and the coffin-bone interpose an aggregation of secretory vessels, forming a juicy elastic process, that prevents concussion, as would necessarily happen at every step the animal takes but for this providence of nature. We have here marked it (cc); but the juicy substance, so produced, pervades the concurrence of all other bones of the foot, only differing much in quality, and in structure a little: between the shuttle and coffin-bones it is more vascular, and the fluid is still decidedly arterial, though the vessels have lost their continuity and merge in an aggregation of cellular structure. Underneath the coffin-bone (at d), it becomes more elastic, thicker, and striated, resembling pale India rubber, which qualities increase towards the heel (at e). These latter rest upon the frog (ff), which is slightly horny, being perforable with a point-knife so far as (g), where it joins the toe of the hoof, more abruptly as the horse is most worked, or otherwise.

At r is the line of the coffin-joint, so much talked about lately at college.

Goodwin would needs keep him in countenance, and talks courteously to prove how the two "harmonize," in the shape of a horse's toe! Who ever heard, before this, of shape harmonising? By the way, these two author-practitioners do not exactly harmonize professionally, we hear from good authority; though the pupil seems to clap his former preceptor upon the back, uncandidly, when he allows that Bracy Clark's jointed shoe may hereafter prove a "Basis for the repose of the profession." Both this and that is real stuff, for men of high pretensions and undoubted merit to fall into.
Coleman and White, who are the authors alluded to at page 442, have persisted in terming this juicy elastic substance "fatty," and fatty frog, at that part which is next above (ff') in our section; whereas, at this place the substance is farther removed from a resemblance to fat or juice than at any other of the parts just described. Although an evident process of the same secretion which ascends in its more fluid state to the coronet, it is here, at the frog, scarcely found gelatinous when submitted to solution. At a public veterinary meeting, April 9, 1828, Dr. Pearson, one of the examiners of candidates, threw his fatty theory in the face of professor Coleman, declaring that he could not, upon careful analysis, discover an atom of fat in its whole composition. The pupils present marvelled exceedingly at this announcement, though we had disabused the public mind on this mistaken notion five years before that day.

The navicula, or shuttle-bone (h), as it has been called, moves in the midst of much elastic substance, resting upon and pressing the back sinew flat upon the strongest part of that substance, above the centre of the frog. This little bone, it will be seen, is well adapted, by its shape, to traverse the lower surface of the small pastern (i), and the lateral edge of the coffin-bone (a), whenever the back sinew (k) is drawn up to lift the foot, as it does, from off the ground, always returning into its place as the foot comes down again. At l is the toe, m is the heel of the foot, and at n is the near
side bar of the insensible frog. At o is the coronet, or coronary ring, and at p the lower end of the large pastern bone.

At a, when the coffin is recently cut through, no difference of structure is perceivable, though upon stricter examination, it will be found at the central part more porous than that which is adjacent to the other bones; this hardness increases towards the whole surface (b b b), where the cutting presents a perfect enamel, as is well represented in the cut referred to, by the excellent chissel of Mr. Lee, to whom the public is indebted for some of the finest specimens extant in the art of wood engraving.

But the contents of the receptacle at a, we have ascertained by experiment to be unequivocally the same glutinous substance (in a state of preparation) as the hoof itself. This process of nature is well explained by the old aphorism that, "arteries entering bone engender bone, those of muscle create muscle," and so on; and the blood thus deposited in the coffin-bone, previous to being dispersed over the internal parts of the foot, partakes of all the qualities of bone, membrane, muscle, and skin—the whole combined becomes horny, being hardest at the wall, or crust, and toe, softer at the sole, and softest at the heels; but all furnished with the material for their supply from the same source—namely, the receptacle in the centre of the coffin-bone (at a).

If our advice be worth any thing—if our earnest
exhortations to investigate the subject effect their object, every man who reads these pages, whatever may be his station in or about the stable or the smithy, will not fail to make a section, or cut, down the middle of a hoof at the earliest opportunity. To effect this purpose, the now industrious operator needs little more preparation than to furnish himself with a cordwainer's knife, and a butcher's saw with fine teeth: if he can add to these the use of a carpenter's vice, in which to fix his subject, he will much accelerate his labour. Having secured the foot upside downwards, he will cut down between the cleft at the heel until he comes to the bone (at b), and the wall, or horny part of the hoof (at g), where the labour of sawing is to begin. The shuttle-bone (h) he will feel and hear rattle forward and backward at every stroke—the horn yields easily. As he proceeds, he will find his trouble lessened, and his views of the matter in hand much enlarged by driving into the chasm his exertions have made some two or three wedges of wood, whereby he will ascertain that the stiffest part of the horn is elastic, even though he should not have adopted the precaution of soaking his preparation, as recommended. He will thus be convinced, that the application of Bracy Clark's jointed shoe is not without its uses. But if our inquirer has soaked his horn, as directed, he will find that the warm water renders it more elastic, and he will conclude that the practice of permitting their horses to stand in the kennels during the issue of hot water from breweries, dye-
houses, rectifier's premises, &c., must soften the hoofs, and indispose them for immediate concussion over the rough stones of our paved streets.

He will also thus discern why we advise, in certain cases, the enveloping the whole foot whenever the application of a poultice becomes necessary to any part of it.

On completing the section, he will discover two branch arteries which, descending into the foot at the coronet near the quarters, have supplied the coffin-bone (a), that occupies the cavity of the horny hoof, with fine blood for its fructification. In other words, the formation of new horn is derived from the blood, which is sent hither in good quantity, and pervades the internal part of the coffin-bone in particular. In this bone the operator will perceive a cavity, or rather three hollow-caverns communicating with each other, in which the horny matter is generated. Or, probably, this is the reservoir for preparing such particles of blood as are suited to the formation of hoof, as it may be required and called for by the process of nature, and the demands of wear and tear, of rasping and drawing, all which must subtract from its quantity, and leave the bone comparatively hollow, and less fit for resisting the hard concussion to which it is liable at every step. This fact may be ascertained by keeping a bisected foot for a few months, when the moisture having left it in great measure, in the cavity of the coffin-bone will be found a yellowish glutinous substance, precisely of the same nature
and colour as that which fills the space between the hoof and coffin-bone (at cc), in the section depicted at page 443: without odour and nearly tasteless, its uses are evidently the supply of new horn, and reparation of waste.

Seeing this curious construction of the foot, we are compelled to allow that numerous accidents may also occur to prevent the supply of blood to the parts, to say nothing of its unfitness at times to carry on its proper purposes. The two vessels before noticed, that bring this supply of new blood descend into the foot behind the small pastern bone, and pass with the back sinew (k) underneath the shuttle bone (h), as may be noticed in the cut. Here it enters the coffin-bone at the sole, by an indentation of the bone designed for the protection of the vessels passing in and out. From the receptacle in the coffin bone, after concoction, the blood issues forth—part of it to lubricate and nourish the shuttle-bone and its adjacent ligaments, the remainder to effect similar purposes elsewhere; but the greater part is attracted, by heat and action of the foot, to supply the horny material of the hoof in the manner we propose to show presently, as well as how it is brought about. Along the whole length of the shuttle-bone, on that side which is next to the coffin-bone, is a groove serving as a protection to certain small blood-vessels that terminate there, and as a central receptacle for the blood that is destined for dispersion. When dried, it is equally inodorous and clammy, with less colour
in it, than the deposit found within the coffin-bone. Now, seeing that it is at the seat of the shuttle-bone, that this elastic-substance is more juicy and plentiful than at any other part, and there is no other means of its escaping the constant concussion of the animal's tread, but by forcing its way along underneath the coffin-bone, and upwards, between the wall or crust of the hoof and the coffin-bone (at cc), and making its way to the coronary ring (at o), no doubt remains that the supply of new hoof is thus carried on, and completed by its descending, thence sparingly, as it may be required.

Those "concussions" before spoken of, as affecting the action of the shuttle-bone upon the posterior point of the coffin-bone, occasion trivial injury at every step, at top pace; more harm arises as the animal is much pushed in his lengths; then heat and fever of the foot supervene, contractions follow, with a train of evils that have acquired different names, thirty in number, but which we have reduced by three-fourths, with a view to simplifying the subject: most of these differ only in situation. Very hard concussions, or a single injury of sufficient magnitude, will produce lameness at once, which most unaccountably received the name of "strain of the coffin-joint," and under which general misconception we shall shortly give it a moment's consideration. Poor old Jeremiah Bridges prefers to call it "numbness of the foot," or stunning; and he is quite as correct as those who talk of a joint being strained, where there is no possibility
of straining it: he who could talk seriously of his "six discoveries, and thirty-two diseases of the bottom of the foot," was yet as correct, in all the essential points, as many of our modern discoverers and patentees.

The student who would push his inquiries farther will next turn his attention to the muscles, ligaments, and tendons, that guide the foot; that lift it up, and permit it again to meet the ground; that it may perform these offices firmly and effectively, or being relaxed, diseased, or ill-formed, they and their functions agree not with the well-being of the foot. Probably he will find it convenient to lay open this part of the arcana of progression by the horse's leg (the lower part of it) previous to severing the foot itself, seeing that the subject will then be quite fresh, and that one part may intelligibly illustrate the other. This is more particularly the case with the flexor tendon, or back sinew, which he will ascertain is of great length, descending all the way from the hock, or back of the knee, behind both pastern bones, underneath the shuttle-bone, and is fastened to the bottom of the coffin-bone.

With the following description before him, he will study the figures 1 and 2 of plate 2; and after removing the remainder of the integuments, and cleansing the bones, he will then perceive the articulations of these, the manner of their working in and upon each other: and as he proceeds to repeat the investigation, he will note the difference that
exists in the shape of a leg taken from a thorough-bred horse and that of a cart-horse; the one small and flat-sided, or sharp before, as best calculated for speed, the other round and heavy, as being made for heavy draught, and to support a large, muscular, and bony frame. While giving this advice, we have presumed he has already examined the superior part of the limb, though the lower bones and their covering come more immediately under notice in this place.

Description of Plate 2—Anatomy of the Foot.

Fig. 1. Back view of the foot, skin removed—(a) the back sinew, or flexor tendon, as it appears above its ligamentary sheath, and below it, descending flat into the foot underneath the coffin-bone (at e); d the coffin-bone, having the sensible sole still adhering to it; (ee,) the lateral cartilage; (b) is the sheath in which the back sinew is enclosed, and moves at every step, but part of the sheath has been removed in order to show the course of the sinew (at a).

Fig. 2. The whole of the ligaments are here laid open by the removal of the flexor tendon, whereby is seen (at a) the smooth surface of the sesamoid bone over which the tendon is ordained to pass; at bb, part of the sheath is turned back, at c is the hollow part of the sheath; at dd the ligament that connects the small pastern to the bone above is shown, with its insertion below (at e), whereby the large pastern is kept in position; ff the lateral
cartilages; \( g \) the bottom of the coffin-bone, \( h \) the toe.

Fig. 3. is a front view of the same, but with all the integuments removed; \( aa \) the sesamoids; \( b \) the large pastern; \( c \) the small pastern, anciently termed the coronary bone; the coronet circling its smaller part (at \( c \)). At \( d \) is the coffin-bone, but represented rather wider than ordinary.

CHAPTER II.

Disorders of the Leg.

Introductory Observations.—All those derangements of the limbs which we come next to consider, are divided, for the reader’s more ready comprehension, into—1st, those of the leg, and 2d, diseases of the foot; for it does not always happen that affections of the leg alone can be properly denominated diseases, whilst those of the foot are invariably so. We before observed, that both, or either, may be occasioned by accident, derived from ancestry, or be the fault of misconstruction and consequent misapplication of the individual’s powers. They may be also considered as, 1st, those of the bones, 2d, of the ligaments, tendons, and muscles. But we will not so classify the several diseases, since each will appear under the respective heads of information; besides which (as will be seen further down), whenever the bones suffer derangement, original or acquired, the integuments follow the
same evil course, as hath already been taught in the first chapter of this volume.

Rest is the primal remedy for all acquired disorders of the limbs, whether those of hard work, of old age, or of accident; but employing the animal whilst yet too young is an universal error, which is but seldom remedied by allowing it rest when lameness once lays hold of him, much less is it capable of being cured by these means alone. The impolicy of this practice, the fruitful source of so many evils, is demonstrable by the custom of the Arabs in the desert country, where, although they load a mare with a foal at her foot, when making one of their forced marches, yet never mount a lame horse, nor propagate from horse or mare which is permanently marked with the effects of over-work. One remote consequence whereof is, that the foal runs no risk of being entailed with a predisposition to contract readily such disorders as we come shortly to treat of; whence we infer the superiority of the Arab breed in this respect. At least, the fact is to be deplored, that most of our stallions of the waggon-horse breed are worked at plough and in the team at two and three years old, too much for their tender years, and permitted to cover mares at this latter early age. The result of this lamentable cupidity of ownership is, that their get are impregnated with one or other of the various maladies we come shortly to enumerate, ere they reach maturity; but the causes and symptoms whereof we have shown are so similar, or proceed so naturally out
of each other, that they differ but in name for situation, in treatment nothing. Higher bred cattle are subjected to the same disadvantages in most breeding studs, in which the breeders prefer to derive their stock from parents which may have been successful at winning three-year old stakes, or probably strained every muscle, bone, and tendon whilst yet yearlings. We owe to the late Sir T. C. Bunbury, of Bildeston, the introduction of this practice on a large scale, which is so evidently harmful to the rising generation—of speedy horses.

Lameness is universally the symptom that denotes disordered limb; it is the only one perceptible for some time, until its continuance throws out some appearance on the surface; and that inquirer who can soonest ascertain its true seat is most likely to find the cause, and to effect a cure. For instance, lameness occasioned by disordered bone, as in ring-bone and bone-spavin, is almost universally ascribed by the stable-men and humble practitioners to strain in the stifles, in the shoulder, or the whirlbone; whereby so much valuable time is lost in applying the proposed remedies at the wrong place, that those two disorders in particular make head almost irremediably before the true seat of ailment is ascertained: and we not only postpone applying the remedies to the proper places, but attempt to cure a spot where no ailment exists. The same species of blunder is propagated when a disease happens to the foot, and the precise cause thereof, even when well known to those employed
about the stable, is kept secret from the owner and the doctor. "Let them find it out," is sometimes heard muttered in the distance; and in order to comply with the unfeeling permission, we pass the hand down over the whole leg and foot from the top to the sole, compare the size of the lame limb with the corresponding sound one, and move the animal about. For without this examination it would be next to impossible to ascertain the precise seat of the disorder, and quite so to apply even the right remedy at the proper place. As an illustration of this position by its reverse, we may adduce the coming on of bone-spavin as that kind of attack which we can ascertain with the greatest precision of all those which lie concealed from our view and touch. It happens, too, that this is one of the few disorders of the leg that admits of cure by early applications, as it is also that which, being neglected, renders the animal wholly useless. When a horse becomes lame of a hind leg occasionally, and that after rest only, the complaint going off on taking a short exercise, we may be quite sure he labours under incipient bone-spavin, provided no other distinct cause can be adduced for his lameness; but should the lameness increase with exercise, then it does not depend upon bone-spavin, but some other malady. Further consideration of the causes, symptoms, and cure of this disorder will be found a few pages lower down.

N.B. When lameness occurs to his horse unaccountably, and the inquiring reader turns to these
pages for information, he had better read over the whole of the next twenty pages; the great similarity of those diseases in many respects, dictates the propriety of this additional trouble, as most of the series (nine in number) will be found referable to the same causes, and require much the same treatment, though differently situated. Throughout the whole of this chapter, the reader will find great help to understanding the details, by carefully consulting the delineations of the leg and foot on plate 2, and the cut at page 443, with the description of each.

1. Quittor.

Under the class of fistulous affections, we spoke of this disease at page 339. To what is there said we may here add, that as quittor is caused by sand crack, by a tread, or the prick of a nail, so will its situation be determined by the precise cause, on the inside of the coronet, or the outside, near the heel, or otherwise, as the cause may have been inflicted; and also, that the cure being effected by harsh means, or burning remedies, these leave the foot disposed to contract other disorders at this region, as ringbone, &c. Hence it follows, that the more moderate the means employed to get rid of this disorder, the less probability is there of the patient’s contracting some other. Therefore is it advisable to try the milder remedies first, unless the quittor is of long standing, and of a very bad sort.
The extent of each *sinus*, and the course it pursues, is denoted by the colour of the soft parts of the foot being black or livid, or else but just tinged, according to its virulence. In order to pursue this examination more accurately, it will be necessary to stop the circulation of the blood above, by tying a ligature round the fetlock joint, whereby the skin of the healthy parts below will appear white, and thus more distinctly expose the nature of the sinuses. The pledges that are to be introduced for the destruction of the pipes may thus be selected of a larger or smaller size, as the calibre of the sinus appears greater or less; as may also the quality of the caustic application be made stronger or weaker, as the virulence may require.

Some hastily use the knife, and lay open the pipes freely along their whole course; and if it descends to near the bottom of the foot, the coffin-bone is usually affected with rottenness or decay, usually termed *caries*. This they hesitate not to scrape off, though, if the patient be of strong and vigorous constitution, exfoliation will take place without extending the operation so far. Indeed, it seldom happens that more is required than to give the disorder free vent at the coronet, whereby the necessity of operating underneath is superseded; for it will be seen, that the ascent of the hoof-making particles from the sole will bring away to the orifice of the ulcer any offensive matters from below; and this process of nature effects the cure. Whenever a sinus leads towards the back tendon,
or the joint, much care should be taken not to injure either with knife or caustic, for a bad-looking seam is then left behind, with lameness that terminates in anchylosis, or stiffening of the tendon, or in growing together of the small pastern (i) and the coffin-joint (a) and the shuttle-bone (k) as seen, in the cut at p. 443.

2. Ringbone.

Causes.—At times a badly-cured quittor, at others ill-shapen foot; which occasions that concussion of the hoof and small pastern bone at their conjunction which causes the hoof to swell at the coronet. Cart and waggon horses with short upright hoofs, that do not sufficiently guard the articulation of the coffin and pastern bones against injury, are most liable to this disease. See what is said of short upright hoof in Chapter I. Sections 9, 10, &c.

Symptoms.—Enlargement of the small pastern at the coronet, in front, extending laterally and sometimes occasioning a stiff joint. Lameness is commonly the first intimation we have of the existence of ringbone, an intimation that is usually neglected, and only ascertained by passing the hand down over the part. As usual with most diseases of the foot, the attendant commonly ascribes the lameness to a strain higher up—of the hip generally, as ringbones afflict the hind foot oftener than the fore one. In the fore foot it consists in the ossification of the cartilage, just above the quarters, at f.f. fig. 2. plate 2.
Remedies.—These may be applied to relieve, but no cure is to be found for ringbone. As high heel usually accompanies the short upright hoof, the concussion of the foot against the ground may be lessened by lowering the heels. Apply blistering ointment to the seat of the disease, and firing may also be employed with advantage.

3. Windgalls.

These appear mostly on the fore-leg, a little above the fetlock, on each side of the back sinew, and consist of small puffy swellings, that occasion no immediate inconvenience, but prove that the animal has been strained in his work, unless it has been brought on by his having been put to it too early in life. They might be occasioned by the sinus of a quittor, pointing towards the pastern joint, having been cured too harshly, whereby the joint oil issues forth upon their being pricked.

*Blistering*, and a run in the straw-yard, are the only remedies, though experiments are often tried (when it is found necessary to sell the animal) with preparations of *muriatic acid*, and muriate of ammonia diluted in water. Saturate a roller bandage herewith frequently, and partial absorption of the windgall takes place.

4. Thoroughpin

Is of the same nature as the foregoing, arises from the same cause, and is equally devoid of immediate consequence to the animal's going. It
consists of a soft flexible swelling on the inside of the hock-joint, as well as the outside, immediately opposite each other; whence it obtains the name of thorough-pin, being supposed to go through the joint. When one of those tumours is pressed it yields, and the fluid it contains is thereby forced into that on the other side; when the pressure is removed it immediately returns to the same state as before.

This disorder has no other effect upon the animal's going, or value, than its appearance amounts to, as it conveys the information of its having been worked too hard, and too early in life, as do all these minor evils we are now considering. How this is effected we have shown in the fifteenth and sixteenth sections of Book I. Like unto the other disorders of this class, blisters and rest are the only remedies: apply the blistering liniment composed of cantharides and spirits of wine: See page 469.

5. Spavin.

Bog spavin is the more common, blood spavin but rare. Both varieties, as well as bone spavin, owe their origin to hard work in early life, in the same manner as just adduced in cases of windgall, and thoroughpin. Bog spavin is caused by the joint oil of the hough issuing into the membrane that surrounds it, and there stagnating under the vein, causes this to swell. The old remedy of taking up the vein by ligature should be abandoned as a long and tedious mode of cure: the circulation
LAMENESS. CAUSES OF [BOOK III.

has then to force a new channel, in doing which ir-
ritation of the parts adjacent is the means of cure,
by promoting absorption; whereas, the same effect
might be produced by blistering, as in the two cor-
respondent disorders just named above.

This disorder consists in a bony enlargement at
the upper end of the shank-bone, inside of the
hock-joint, a little below it. It belongs to the hind
leg only; and if not undertaken in time becomes
incurable.

Caused by the same kind of cupidity as the last
mentioned diseases; and like these is generally mis-
taken for some strain at the superior part, as the
hip-joint, until by delay all our endeavours are
rendered hopeless. At the seat of this disorder
the leg is composed of three bones, which fit to-
gether into one common cavity at the hock; and
notwithstanding they appear as close together as
one bone, yet possess separate motion to give
elasticity to the animal's tread, and assist him in
the act of progression, as may be observed in the
working of his haunches when the horse is going
at full speed, or making a standing leap. By
mounting the colt whilst too young to bear the in-
cumbent weight, by pushing him hard in his work,
as well as by working young cattle at plough, a
practice some breeders of heavy horses injudiciously
adopt, these bones get strained asunder, as 'twere,
and inflammation takes place.
As almost every one knows, by misusing young colts in the manner just described, they become cat-hammed, if they do not derive that particular mal-conformation from parentage, as before hinted (p. 444), and is more scientifically accounted for in the first chapter of Book I., page 50. Generally it happens that horses so formed are good, easy goers, brisk and active; but though well adapted for light weights, are utterly incapacitated from undertaking horseman's weight at speed, until they are full mouthed. If heavily mounted, or hard driven early in life, they invariably throw out a curb or spavin. The shoeing-smith frequently contributes to the contraction of bone-spavin without knowing it, by turning up the heels of the shoes in frosty weather unevenly. In the same manner, when the inside heel preserves its roughness longer than the outer heel, it is clear that this last must bear lowest, and further contribute to the evil strain that cat-hammed horses are ever liable to, about the hock.

Symptoms.—Inflammation is scarcely perceptible at first, or any other symptom; and as it is vitally necessary that we should apply the remedy thus early, we must employ the discriminating test described at page 457. If the existence of adhesion, which constitutes bone-spavin, be not discovered in the manner proposed, the disorder proceeds until it may be perceived upon comparing the hocks together. At first the inflammation is but trivial, when the horse is also lamest; but when
time has been allowed to unite the bone, the heat and enlargement increase, and the spavin is incurable, but the lameness is lessened.

Cure.—At the commencement only it may be effected easily, by simply blistering the part all round the hough, in such a manner as to raise the blister to a good extent. Generally, in bad cases it would be advisable to repeat the blister; in which event let the former one be first well cleansed away with Goulard’s extract, diluted with water. But should the duration of lameness and degree of swelling give reason for apprehending that the adhesion is uncommonly extensive, let the part be fired previously to blistering. Be careful to keep the horse’s head up whilst the blister is operating, and subsequently dress with hog’s lard; but do not use any greasy applications previously to blistering, as these only tend to harden the skin, and so obstruct the perspiration and absorption which promote the cure.

Making the shoe thin on the outside at the heel, relieves the pressure when the horse is worked; the contrary form of shoe is conducive to all diseases of the leg bones.

7. Curb.

Cause.—Inflammation in the sheath of the flexor tendon (b, fig. 1, plate 2), a little below the point of the hock, where the sheath is attached to the muscle. Like spavin, curb mostly affects young horses of the cat-hammed built, whose legs stand
too much under the body, and which have been worked prematurely hard, as in the case of bone-spavin. Indeed, the two diseases bear so much resemblance to each other, in cause and symptoms, except only as to situation, that we feel no difficulty in referring the reader to the preceding page for our description of these, only premising that he cannot discover the coming of a curb, by any other means than lameness, and comparing the two legs to each other sidewise, when a diffused swelling may be seen, but very little heat felt, by reason of the disorder being deep-seated.

Cure.—It may be effectually removed at first coming on by blistering, as in case of bone-spavin; but when the disease has lasted a long time, firing must be resorted to with the same precautions as before recommended. Ease may be afforded by adding to the thickness of the heels of the shoe.

8. Splent

May be looked upon as a disorder of the fore-legs, though occurring on the hind ones, at times, under another name.

Cause.—Working of young horses before they have acquired sufficient stamina, or on labour which is much beyond their strength, as in case of spavin, curb, &c. to which the reader is referred, and the concussion which the leg receives at going upon hard ground, stones, &c.

Symptoms.—Frequent lameness that goes off and returns without apparent cause for either, before
the splent shows itself upon the cannon, or shankbone, which it does at length on the inside. Similarly hereto, it affects the bone of the hind leg, and then acquires the name of bone-spavin. Inflammation of the skin is soon felt, and the horse goes lame until the splent is completely thrown, and afterwards he does as well as ever, except retaining the splent mark, perhaps; but severe cases occur, that do not terminate so favourably. Such happens when the leg undergoes very rude concussion, that causes the enlargement and rupture, which constitutes the disease, at the hinder part of the leg, where it meets with tendons or the suspensor ligament—(See back view, plate 2, fig. 1, 2.) The lameness and the inflammation are then at their highest state of excitement, and the splent requires careful attention.

Remedy.—But should not the horse throw out the splent on this last mentioned dangerous part, and become lame, he will yet suffer much in all ordinary cases; for the enlargement of the bone strains the membrane which covers it tightly, as described in Book i. sect. 17. For this purpose apply a warm stimulating embrocation, which affords relief in the more favourable cases; but when the splent rises under the ligament or tendon, blistering or firing must be resorted to. The latter, however, is proper only in extreme cases, and only to be adopted when blistering is found inadequate to the purpose: if the swelling is hot and tender, firing would have the effect of enlarging the whole
bone of the leg, and even the blistering liquid is improper when this symptom is highly prevalent. Rather let the heat subside, or assist it in doing so by means of Goulard's extract, diluted with water, frequently applied. When this has reduced the heat, employ the following

**Liquid Blister.**

Cantharides pulverised, 4 drachms. Mix with sweet oil to the consistence of treacle, and apply the same twice during the day; thus, —Let the hair be clipped off close from the part, and all round the leg, and the blister well rubbed with the hand (covered), for five or ten minutes. If this does not cause further swelling and the discharge be of a clammy nature, a third application of the liquid blister becomes necessary. After a day has elapsed, dress two or three days with hogs' lard, and the patient may be walked about, to get rid of the stiffness. It may be proper, after this, farther to reduce the heat by more applications of the Goulard's extract, as above.

*Shoeing* is supposed to occasion splents sometimes, it being the practice with most *smiths* to make the inner heel of their shoes thinner than the outer; and the inner heel being also lower than the outer, occasions the splent bone to receive the concussion more sharply than the outer one; for, as was before observed, splents oftener occur on the inside of the leg than on any other part of it.

Scurvy eruptions on the bend of the knee-joints, or on the corresponding bend in the hock joint; the first mentioned term being applied to those eruptions that appear upon the fore leg, the second, sallender, is confined to those of the hinder leg. A crack, with much soreness, accompanies both.—The cause may be found in gross habit of body, attended by suppression of some ordinary evacuation, as stool, urine, or perspiration; therefore, to

Cure the patient, restore the defective evacuation by giving the purging-ball prescribed at page 244, or that at page 245, according to circumstances; or a urine-ball, or the emetic tartar, at page 190, or 387, in smaller doses, and the scurf decreases until it wholly disappears.

Let the hair be cut off close from the part affected, and the scurf well washed with strong soap-suds, and then rub over it daily, of the

Ointment for Scurvy Eruption.

Red precipitate powder, half an ounce.
Hogs' lard, 2 ounces. Mixed well together. Sometimes, a poultice, in which is introduced acetated litharge, becomes necessary, when the eruption is divided by a gaping crack, which the ointment may have occasioned. The blue ointment of the shops is employed by some instead of the above ointment: the effect is not materially varied by this adoption.
These are the most deceptive class of ailments attributed to the limbs of the horse; for many such are spoken of in the most confident manner which do not exist in reality, whilst others could not possibly happen to the parts indicated by the names they commonly bear; yet shall we fall into this old method of titling the various affections of the limbs in order to render what we have to say more generally understood. Our neighbours, and rival veterinarians, the French, in the instructions issued to their smiths of the army, went a little farther in their complaisance to error: "All swellings of the tendons from the knee to the coronet, or from the hock to the heel, show an extension or strain of the integument. Take off the shoe and pare the foot." In fact, their practice of ordering rest in all cases of strain, which often effects a cure with very little further assistance, could not be more assuredly complied with than by thus taking off the shoes; for the Marechallerie were ill able to retain their sick horses in quarters, upon urgent occasions of active service, unless they could demonstrate the fact upon the view to their superiors, which this taking off the shoes would shew without fear of contradiction.
By this general mode of forming their judgment as to the cause of all swellings before or behind, we may perceive they included all "extensions" of the bone in their notions of a strain, and treated spavin, splent, curb, strain of the tendons and ligaments, all in the same manner at first. Of these latter-mentioned we come next to consider the distinguishing symptoms and most appropriate methods of cure; and we will here candidly allow, at setting out, that our neighbours took a correct view of the general cause of all lameness: those strains which occasion inflammation of the ligaments, tendons, and muscles, always communicate fever to the foot*, whence arise thrush, canker, sand-crack, &c. &c.

We very improperly, so far as precision is concerned, term all lameness of the tendons, &c. a strain, though it may arise from any other cause, as frequently happens, viz. a blow given by the toe of the hind foot, in hunting over heavy lands, when the fore foot is detained too long in the ground, coming in contact with rolling stones in leaping, the kick of another horse, &c.

The word strain, as here employed, is evidently used in the wrong sense: it should be sprain, i.e. bent or twisted out of its proper position. To strain, or stretch any thing long to a greater length, as when the back sinew is strained or enlarged so as to permit the pasterns to slope or bend down, as in mild cases of "breaking down" would be a more

* Turn back to pages 53, 54; and see page 462.
accurate expression for this particular ailment, but certainly not for the twisted *sprain*.

1. *Sprain of the Shoulder*.  
Horses that are weak before and low loosed, with an unsteady tread, are most liable to contract this disorder; which consists in a twist or sprain of the strong muscles that attach the shoulder to the body. There being no socket for the shoulder-blade to rest in, as is the case with most other animals, the horse is very liable to incur this disaster in a petty degree, whenever his progression is accelerated to the utmost of his powers; but we must guard ourselves against placing entire reliance upon the hastily-delivered opinions of empyrics, who boldly pronounce when they hope to deceive, and expect belief from the credulous.

*Cause.*—Much the same as those which occasion concussion, blows, and numbness of the foot, with their consequences, which we consent to call "strain of the coffin-joint," without the most distant possibility of knowing whether this misfortune ever has happened. When the horse is subjected to any rude accident, as a kick, or his load becoming disordered, or being thrown down, or slipping on pavement, ice, &c., or treading on a loose stone, he is very likely to incur strain of the muscles of the shoulder. See conformation of the shoulder, in chap. i. page 40.

*Symptoms.*—Decided by swelling upon the chest, or at the top of the shoulder; but we think it
desirable to ascertain whether the accident has taken place before this symptom becomes apparent. Lameness immediately succeeding any or either of those accidents; which may be distinguished from a strain lower down by the animal’s drawing his toe along the ground, from inability in the part to lift it off the ground; but when he throws out the foot in a semicircle, described by the segment at page 42, this shows that the hurt is chiefly confined to the lower part of the shoulder near the elbow. Taking up the foot, and bending the limb, will further prove the existence of strain in the shoulder, if the animal evince pain; whereas, if it lie in the foot, and not in the shoulder, the lame leg can be moved as supple as the sound one. The difficulty of ascertaining the real seat of lameness is sometimes so very great, being entirely invisible, that the groom seldom hesitates to assert his belief that the horse may be gammoning, or “shamming Abraham:” this uncertainty has put us upon all sorts of expedients to find out the real seat of the disorder. For this purpose, hold up his head high, and after comparing and finding no difference in the shape of his two shoulders, let go the head, when he will be observed to flinch upon bringing it towards the affected side. Let a person rattle some corn in a sieve at a distance behind, now on this side, now on that, and he will be observed to evince pain at turning the neck so as to strain the affected side; not so if the pain be in the foot, of course. As the horse will step short, and also throw out his
leg somewhat in a semicircle, when he has received a prick in shoeing, this latter sign is not to be taken as finally indicative of "strain in the shoulder," until the foot has been examined, and the shoeing-smith questioned as to his skill and carefulness.

**Cure.**—If the injury be considerable, as when the horse has been thrown down, he should be bled at once, in the plate vein when it is local, but in the neck when the injury has been more general. A laxative ball, or a purgative, must follow, as a matter of course, proportioned to the actual state of his body at the time. A fomentation of camomile flowers, or of scalded bran, should be applied largely and assiduously at the chest and inside the elbow, and these remedies, with rest from all labour and exercise, generally perfect the cure.

When the swelling is great, but not extensive, as in the case of a kick, spirits of wine, in which a fourth of its weight of camphor has been dissolved, should be rubbed in. This will supersede the necessity of walking the horse too early, with the hope of recovering the "use of his limb," by promoting the lymphatic absorption. A rowel is sometimes employed, when the heat and swelling are very high, with good effect; but the old system of previously boring and blowing, and laying on "a charge," is exploded as barbarous and inutile. On the symptoms abating, let the convalescent horse have a loose stall, and in proportion as his action may be free from lameness, so should be regulated his return to walking, to exercise, and to
work. Before he can be fit for his former occupation, it generally is found best to give the horse a run at grass; but previously he may try his powers in a contracted plot of ground in the homestead, to prevent his indulging too freely in exercise, seeing that he is very liable to a relapse, which is generally more difficult to overcome than the original attack.

Swimming the horse "for strain in the shoulder joint," was a favourite remedy formerly, but is deservedly exploded, although we could be certain that the joint intended to be cured were the elbow. This accident, however, does not happen often: we never saw a marked case, and merely deem it possible; yet has the practice still its advocates. And it may be serviceable in other respects, as the muscles are thus brought into play, and the whole limb employed in quite different kind of action to that of walking on terra firma. Some persons submit their horses to bathing, by entire submersion; an operation that was performed most adroitly, about thirty-five years ago, by a stableman named Denis Lawler, in the bay of Dublin. His manner was to ride his horse to a convenient depth of water, and then jumping forward suddenly on the animal's neck, thus souse it head-foremost to the bottom. The feat caused great marvel at the time; but not so the total disappearance, upon one occasion, of the performer: poor Denis is supposed to have received a kick to the bottom, and his body drifted out to sea, as his Howth friends
heard no more of him after that, though "New Harbour" underwent thorough repair since poor Lawler's last kick.

2. Strain of the Whirl-Bone (Hip-Joint.)

A supposititious disorder, which is more frequently found to be a tardy attack of bone-spavin, that is slow in coming forward, and upon which M. la Fosse has thought proper to be very facetious: "a horse has the spavin, or he has it not," says he; "it is not like a jack-in-a-box, that waits to make his appearance when you pull the string." Either spavin or strain of the whirlbone, he concludes, must be the disorder of the hind leg, when the animal draws its toe along the road, as described just above as being a symptom of strain in the fore leg. When the animal has received injury in the region of the hip, the camphorated spirits recommended in a preceding page (475), should be applied; but if the heat, swelling, and tension do not abate by this treatment, blister the parts with the mild blister No. 3, at page 485. This application, with rest, is adequate to any ordinary case of hip-joint accident.

3. Strain of the Stifle.

Simple "lameness" would better designate this so-called strain. The same remedies as those prescribed for whirl-bone strain will apply to this part; also fomentations, physic, and if the case be invertebrate, a rowel, &c. &c. one after another. Cam-
phorated spirits, or ultimately a mild blister, are useful and proper, according to the circumstances just set down.

4. String-Halt.

Cause.—A cold, and consequent rigidity of the sheath of the flexor tendons, whereby the membranous connection between them, and the tendo plantaris is destroyed.—See page 443.

A catching up of the hind leg at every step the horse takes, constitutes what is termed string-halt. It is one of the incurables; but this consideration shall not deter us from observing, that this over-action of the hind leg may be brought about by art, or rather the ingenuity of man operating upon a known function of nature.

The cause, naturally arising, is very obscure; but the horse-exhibitioners, having occasion for much show at their amphitheatric courses, sought to bring on this "high show" by puncturation. To them let the secret belong; it is barbarous and unseemly.

5. Strain of the Back.

When the immediate covering of the bones, described in Book I. at page 65, become relaxed, and thereby fail to hold the joints together sufficiently firm, the consequence naturally arising from this circumstance is, that they bend a little out of place, at every movement the animal makes, and the least accident confirms the strain, or rather sprain. Merely straining or stretching will effect this evil
at times, though that be no greater than an effort to relieve nature by a *motion*. The very great number of joints in the *back-bone*, added to its horizontal position, render it more liable to *sprain*, perhaps, than any other joint connecting longer bones; and this is the reason that the short-bone joints of the foot are so liable to give way at apparently trivial concussions.

*Cause.*—Mostly affecting draught cattle of the heavy kind, and principally incident to cities and towns, where dray and cart-horses are obliged to *turn* short upon slippery stones, we may ascribe this disorder to what is called a *wrench*, or twist in the human practice. The *steady pull*, unattended by a *turn*, is not likely to occasion *hurt* of the back, be it never so hollow originally; because the effort that is made to pull a great weight causes the joints to press straight against each other, every *capsule* being then filled with its next corresponding convex bone.

*Symptoms.*—A kind of separate motion for the hind quarter, compared to the fore one, of which the exact perceptible division is the seat of the injury. Sometimes it appears as far back as the 4th lumbar-spine, but when farther forward than the 15th, (at O. 24, on the frontispiece,) it affects the respiration, and with it other vital functions, and the animal suffers in his *general health*. It may be muscular or ligamentary, or compounded of both, in which cases the parts adapt themselves to the derangement that has taken place, by thickening their sub-
stance, and the first lameness decreases greatly: in this event the horse's condition is not at all affected. While staling, his efforts are somewhat ludicrous; as are also all attempts to make a trot of it when out of harness. These symptoms have deceived some persons into the belief, that the one or the other exertion has caused the strain; whereas it is only the earliest demonstration of it to the observer.

Remedies applied early may assist nature, but the lameness never can be cured completely. If the wrench or sprain has been of a violent sort, as in the case of "shoulder strain," let the animal be bled to a good extent, i.e. from three to five quarts, according to the quantity or degree of violence he has sustained; for it usually happens, that it has been strained all over, in various parts. Two dray-horses, which were employed in pulling beer butts from the cellar of a public-house at the corner of Homer Street, being backed too close to the steps, fell in, the weight of the hinder horse dragging in the fore one upon him. Much contusion was the consequence, as well of the accident itself as in dragging them out: they were in fact strained all over, so that they could scarcely stand for a while. Bleeding copiously, however, to the amount of six quarts, reduced the tendency to inflammation; and although they might be pronounced hurt all over, and the hind horse in particular, both did well after physicking, and a few days of light work.

We have found a fomentation of hot vinegar of very great service, in a well marked case of recent strain;
the plan recommended by White, of administering it by means of a woollen cloth or rug steeped, and loosely wrung out, being followed. A fresh sheepskin, just flayed, was applied immediately, and the lameness sensibly lessened, after the third day, and applying the fomentation twice a day.

Cause.—Back-sinew is the vulgar name for the tendon which the reader will find depicted in the section of a foot at page 443, and marked (k). It ascends behind the small pastern (i) and large pastern, up to the knee-bend of the fore-leg, and to the hock-joint of the hinder one, respectively. In plate 2, fig. 1, (at a), this sinew is again shown, where it emerges out of the heel, and enters its sheath (b), to which it is attached in a certain degree, by means of a membranous process adhering from side to side, and capable of distension or relaxation. The sheath itself is attached to the two pasterns, of which it thus becomes the tendon or support; whence the back sinew and its sheath, or flexor, together obtain the plural—tendons. Within the sheath is secreted a milky fluid, intended for lubricating and defending the parts during the very great action to which they are liable in every effort of progression. As happens in all other secretions, this one sometimes fails to produce enough for the intended purpose, when the sinew and its sheath adhere together, or at least do not act with freedom; the consequence whereof is lame-
ness in a greater or less degree, which may be temporary only, or become permanent, according to circumstances. If the dryness and consequent adhesion be trivial, as happens after hard work and a night's rest, the horse, upon getting warm, loses the lameness this deficiency has occasioned, for the secretion has been thereby renewed, and the lubrication is now effected sufficiently; but the horse falls lame again next day, probably, and if he cannot be allowed rest, 'tis 7 to 1 that he becomes permanently lame. In this respect the French beat us hollow (as just before remarked at page 471), though they do not profess humanity so sensitively as the English; and even the Arabs, though robbers by profession, by habit, and inclination, are too sensible of what is due to a faithful animal in distress, to travel on lame horses.

Symptoms.—That sort of strain which consists of relaxation of the back sinew shows itself by the horse going low upon his pasterns, in consequence of its "carrying high," or being trotted constantly in harness. Occasional lameness sometimes ensues in that fore foot which beats, or has the lead at setting out—generally the off one; inflammation of the whole foot may be felt by comparison with the heat of its fellow, which is aptly enough termed "fever of the foot" by the old farriers. This is a very puzzling kind of lameness, no other symptom than those presenting itself for us to ascertain the exact cause; and of course the less observant persons are very likely to apply the
wrong medicine, and render the horse a disservice instead of doing him good. The lameness sometimes goes off, without any treatment whatever but rest; it is, however, more frequently accompanied, or followed, by some disease of the sole, in consequence of the secretion of horn in the foot being obstructed. Sand-crack, frush, corns, are among these evils, arising from supernatural heat.

Whenever it so happens, that the secretion does not restore to the entire tendons their original motion, it follows that some part adheres to another; inflammation is the consequence, and the horse becomes worse and worse every day he is put to work, the lameness never leaving him altogether. When the adhesion begins extensively, the inflammation and swelling are equally so; the pain is then very great, and the lameness complete and permanent. This denotes the disorder called "strain of the back sinews," otherwise, "strain of the sheath of the tendon," the sheath being technically termed flexor tendon. In very bad cases, or where a slight attack has continued some time, the ligament that passes between the back sinew and the pastern bones becomes greatly diseased, and conducts the inflammation to the foot, affecting alike the sole, the coffin-bone, and the hoof, with heat.

Violent inflicted strains, and consequent swelling above the fetlock-joint, or over the superior parts of the leg, when the lameness is usually very great, require strong physic; and the inflammatory symp-
toms, when running high, with a quick and irregular pulse, should be lowered by bleeding. Apply fomentations of bran, or a poultice of the same, or of oatmeal, in which the saturnine lotion has been introduced, as much as it will bear. When the great heat of the part has caused dryness of the poultice, saturate it externally with the saturnine lotion, either by soaking cloths in it, and spreading these all over the part affected, or in a poultice as above. This latter mode is an affair that is generally very ill performed by stablemen, and he among the attendants upon sick horses who is most expert at making bandages, ought to be looked upon as a valuable servant.

After this treatment has reduced the inflammatory symptoms, but not the swelling and lameness, apply opodeldoc, which may be made as under, viz. Embrocation No. 1. If this does not fully succeed in the course of three or four days, recourse must be had to No. 2; and if this does not prove sufficiently stimulating, apply the mild blister No. 3.

*Embrocations for Strains.—No. 1.*

Spirits of wine, 4 ounces,
Camphor, half an ounce,
Soap, 2 ounces.

Dissolve the camphor in half the spirits; mix the remainder with the soap, and then put both together. Rub the parts assiduously twice or three times during the day.
No. 2.

Crude sal ammoniac, 2 ounces,
Vinegar, one quart.
Mix in a bottle, and rub the parts twice daily. Let a long bandage, dipped in the embrocation just prescribed, be passed tightly round the parts, beginning at the bottom and making it fast above the knee, or the hock, as the case may be. Moisten the bandage after it is on.

No. 3.

Cantharides, in powder, 1 drachm,
Spirits of wine, 2 ounces.
Mix, and rub it on the part. Although this acts as a very mild blister, the horse's head must be tied up for a few hours while it is operating.

A course of treatment that has been followed in this manner steadily, and with due caution, seldom fails to restore the animal to a comparative soundness, if not completely so; though the swelling may remain after the lameness has ceased, it generally subsides when the convalescent animal can be permitted to walk out for a little exercise, which should take place gradually, and the use of a loose stall allowed, than which there is not in the whole catalogue of remedies a more certain adjunct to be found. Going out too early after apparent recovery is very likely to bring on a relapse, and a relapse, as every one knows, is always more difficult to remove than the original disorder. Time
is required for the injured parts to recover their former posture and strength, if that event ever arrive. *Firing* may be employed after a while, but is very often resorted to prematurely, before the tendons and ligaments have recovered position, or absorption has reduced the muscular parts to their former size, and restored their action. When three, or four, or five months of moderate labour give reason for believing that these events have taken place, firing is likely to prove highly serviceable by bracing the whole together in a tight skin, much resembling, and greatly excelling the long bandage prescribed with the embrocation No. 2, in page 485. The reader of discernment will please to note, that if the said artificial bracing be found to lessen the lameness in that early stage of the disorder, no less will the bracing of the natural skin by firing be found beneficial when healthy *action* is restored, but not perhaps the former *strength*.

More ruinous than any preceding kind of *strain*, this accident is moreover remediless, and happens mostly to the better description of horses; to young racers in training, at their trials, or in the actual race; to hunters in leaping, or during a hard run over a heavy country.

*Cause.*—Simply relaxation of the tendons and ligaments that support and keep together the pattern bones. Grooming overmuch by hand-rubbing
the heels until the tendon is divested of most of its muscular covering, and it becomes naturally cool and elastic *. That race, or breed, of the horse which has low pasterns, and high goers, are most liable to break down upon being pushed.

**Symptom.**—None precedes the actual breaking down, or falling of the animal, though it sometimes runs many yards with the large pastern protruding through the skin upon the ground, in which state, we have it upon record, the courageous animal has come in and won the stakes, to obtain which it has thus paid for with its life: in this case the suspensor ligament has been ruptured or torn from its true position †. Not always proceeding to this frightful extremity, however, the animal is ascertained to have broke down by the fetlock joint nearly touching the ground: in this case the back sinew and ligaments under it are found to have relaxed or given way.

**Cure** there is none, though ineffectual attempts are usually made to doctor up the ruined animal for sale. Apply the same remedies as those recommended for strain of the back sinew in page 484, of all which, firing promises the least benefit of any. Yet does heat, atmospheric and animal heat,

* The hand-rubbing causes lymphatic absorption of muscle, until tendinous substance supplies its place, and as the former state had been too fleshy and warm, so is the latter too cold and elastic.

† At the Lancaster races, 1825, Sir P. Musgrave's Walton colt broke down in the third heat. Soon afterwards the Tiresias colt of General Sir John Byng also dropped down in a similar manner, but at the covert side: it is said to have made a previous start forward.
possess a tendency to brace or contract the tendons, whilst coolness preserves the juices, and with it the elasticity of this particular integument, when the remainder of the coverings are least incommodeed with muscle.

CHAPTER IV.

SHOEING.

Terms and phrases, in all matters connected with the arts of life, should convey a good and distinct notion of the thing spoken of. This does not always happen in our day, formerly never, and proved a vast stumbling-block to the advancement of science; but whoever termed the horse-shoe an "iron defence" was a happy fellow, and deserves well at our hands, inasmuch as his appellation is goodly descriptive of the thing intended, and tells plainly what a shoe ought to be in reality. If not made of sufficient quantity, and of a proper material, it proves inadequate to defend the hoof from injury; if made too heavy, or ill-shaped, the shoe becomes the cause of grievous offence, of pain, heat, and contraction of the horn, with its train of evils. Any workman may learn by practice, and, therefore, every one ought to know, at least, when too much or too little is applied. Some feet have the
wall very thick, and the shoe will require a good bearing; if very thin, it cannot carry a heavy shoe, though it stands most in need of defence. Again, the horn of some horses' feet is so well-tempered and stout, that they might be permitted to go without shoes without danger, if not worked upon stony roads. Time, however, and hard work, and the heat of the blood, occasion brittle hoof, and distortions, with numerous disorders that attach to the foot generally, or belong to the sole only.

When these ailments begin to show their effects, the actual shoe-maker, or "fire-man," as he is called, must adapt his work according to the new pattern thus cut out for him, and here begins his ingenuity: in some extraordinary cases he will even have to adopt a different shaped defence for the same set of feet; but in all cases, and under every circumstance, he must fasten them on firmly to the horny wall of the foot by nailing and clenching; he who performs this office being termed the "door-man" in London, where labour of every kind is very much subdivided. Both will find, in the ensuing pages, that we have not been unmindful of the duties they have to perform. To the latter of these men falls the task of preparing the hoof to receive the shoe, by removing the superabundant horn; but if horn do not so abound, he should cut away scarcely any, lest the defence come off for want of sufficient attachment. What is worse, by paring the sole inordinately, the bones within are pressed out of position when the animal again puts
foot to ground; and the wall having now no resistance in the horny sole to keep it expanded, it contracts and becomes shapeless and diseased. Partial parings overmuch produce partial accidents from without, and engender diseases within, which have received a great number of names according to the situation, but all having their origin in this or some such injury, and all producing contracted hoof and sole. The importance of avoiding this baleful practice may be deduced from the great anxiety of our ancestors to particularise, by so many different names, this single disease of the sole arising from contracted hoof. For, whenever constitutional diseases fall into the foot, they never affect the sole, or any part of the bottom, unless attracted thither, and brought into baleful activity by accidents or contraction of the hoof, by reason of this paring and rasping away of the natural defence. For example, inflammation of the lungs affects the fore feet with fever and chest-founder, whilst the like attack upon the urinary organs affect the hind feet with thrush *. Those

* Meaning of course the kidneys, ureters and bladder, with its neck; which latter is liable to disorders the bladder is not subject to. But a very common and really very vulgar blunder prevails of dubbing the bladder alone with the whole title of the urinary organs; whereas the bladder has less to do with the formation of urine than any of the other component parts of those organs; nor is it the seat of any disorder that is not first communicated to it from the kidneys. Yet does the writer, who is admired as the author of Nimrod’s letters, fall into this double offence, when copying these three or four sentences into his long chapter on “foot lameness,” which he does
diseases are constitutional, or residing in the blood, and may originate sand-crack, fever in the feet, quittor, and the like, but produce no curb, canker, surbating, corn, or those other twenty alleged disorders of the bottom of the feet before alluded to, unless the foot be harmed in some manner or other.

Under each of those heads of information, we shall presently place before the operative reader a few plain and intelligent precepts, accompanied by some fatherly admonitions; for most assuredly, that teacher who contents himself with telling the learner what is necessary to be done has but half performed his duty, if he leave uncorrected certain long-standing errors, which he knows to exist, and to have received the sanction of ages that were confessedly working in the dark, as regards horse-shoeing above all other operations. But the method of performing this operation is avowedly not to be taught in its rudiments, upon paper. Practice is indispensable, manual labour requisite; and much of it, conducted by an intelligent mind well versed in books, is necessary towards forming the proficient shoeing-smith. Hitherto, however, from the nature of the black-smith's trade, its laboriousness, and the deficiency of general education down to a late period, most of the operatives in this branch of

without acknowledgment; and intending honestly to amend our want of precision, he substitutes the bladder (as being more particular) for our "urinary organs," and thereby destroys the whole passage, on which his argument mainly relied for support, because the bladder effects no such lameness.

y 6
mechanical labour were precluded from acquiring the additional information that books contain, after they had once adopted their future calling. Error and prejudice laid fast hold of our ancestors for ages; and the darker it seemed for the very little glimmering light which did but shine to render it still more visible. But the prevailing national desire of acquiring the minor school endowments, promises a different result at the present day, and particularly on this occasion, when *Science* has been disrobed of her cloak, and the niceties of *Art* are sought in language that all can comprehend.

The shoes affixed to the feet of their horses by the continental farriers differ materially from our own, and from each other; which proves, that no fixed principle is acknowledged by either of them; though *the English* and *the French* assimilate together the nearest of any, and are those, it is apprehended, that approach nearest to perfection; notwithstanding the controversies and bold assumptions of superior wisdom, and the "patents," that enabled a few persons here to give themselves airs, and to set up pretensions they have miserably failed to substantiate. The jointed shoe, for instance, of Goldfinch, of B. Clark, (see page 500,) and of Rotch, which is the best modification of the old semi-oval defence for healthy feet, was preceded a whole century by the French author of "Le Cheval," a folio French work, noticed by *Mr. Bee* in the Annals of Sporting for 1823, and by *Wallis* an *Irish* author in 1766, or earlier.
Practical Precepts.

The shoe. In quantity or size, the common defence of the full-grown horse's foot is made half an inch thick at the toe, but near the heel one fourth less; here, also, it must be made narrower by the half than at the toe, where it is an inch wide, and so continues round to the quarters, lessening away towards the heel, where it is but half an inch wide. Very near the outer edge a groove is made, not too deep, but sloping from the side next the rim, in order to throw the heads of the nails slanting, when the final hammering down takes place. A practice prevails with us of making this groove, called fullering, much too close to the edge; and to so great an extent does this mistaken notion prevail, that he who could so make it nearest to the edge without cracking the rim was long considered the best workman. This, however, is not the most
approved method of our times; for the nail-holes that are to be punctured in this groove are thus brought too near the edge of the horn, so that the nails do not hold fast, unless driven and clenched high up on the hoof, which also is an exploded part of practice. Neither should the fullering be continued round the toe, nor to the quarters, lest you weaken the defence where its protection is most required.

Iron is the only proper material, and the toughest is the best defence, as it affords a small degree of elasticity in action, is least likely to crack, and is capable of being hardened at the wearing points, at will. The toe alone is usually hardened at the time of making, unless in winter, when it may be found necessary to turn down the heels, termed frosting, when these may also be hardened, or steeled.

Some persons frost all their shoes in winter, by fullering them over all the ground surface; but this rough soon wears away, or is of little service from the first. On turning the heel down, a crippling gait is produced if the rough be long, especially with heavy horses, having low hoofs, which may be counteracted, so long as the roughing lasts, by turning down the toe also, and steeling both. But then the necessity of frequently removing the shoe, and thus impairing the wall or crust, may be remedied by making screw-holes in the ground-surface of the heels, and providing a suitable supply of screws with steel heads, that may be applied

1
and screwed on fresh every day, if need be. Sizes of course would vary according to that of the horse and shoe.

Shape.—For sound feet, both surfaces of the English shoe are made perfectly flat, the inner rim being thinner than the outer. The shoe extends all round the edge of the wall or crust, which it is desirable to defend, and terminates where the bar and crust join at the heel. A curve upwards, at the toe, to prevent tripping, though sanctioned by authority, and carried to an extreme by Goodwin, and others, is seldom desirable, even with heavy horses, or those which go close to the ground, and is well met by a modification of the German and French method, of forming the shoe wider than ours, and consequently less pointed at the toe. The toe being then rasped close to the shoe, no tripping takes place on that account.

The French form, or shape, differs from our English shoe, in being made wider and approaching nearer to a semicircle, and instead of being flat next to the hoof, is hammered hollow, which renders the ground surface convex; a mode of proceeding that suits admirably with their coarse footed horses, and comparatively harmless roads [meaning their petit chemin, and the sides of their grands chemins], but is inadmissible in England, excepting perhaps with our agriculturist owners of the like ordinary cattle. They also make their shoes as thick at the heel as at the toe, which is a transgression against the general precept, at page 489, that we cannot
reconcile with propriety: what is more against the French, they take little heed of hardening either toe or heel. An adjusting curve upwards, which they give to the toe, could add nothing to the security of a horse's going along safe on our roads, whatever it might do on theirs; but their system of punching and nailing is altogether so excellent as to deserve imitation more extensively than it has hitherto been honoured with, and is described with due discrimination lower down. The horn at the toe would, of course, be made of a fit shape to receive such a form of shoe as the French; and we have reason to believe that it affects the toe of the coffin-bone in process of time, which also becomes curved upwards, precisely after the form thus factitiously given to the horn, and doubtless gave rise to the discrepant representations adverted to at page 445.

On finishing off fine work, let the inside of the edge or rim of the hinder shoes be well bevelled off towards the ground, and rounded, to prevent the possibility of coming in contact with the fore foot: with horses that are apt to forge, the necessity of keeping the fore-shoe heel short, so that it may not project beyond the natural heel, should never be lost sight of. So, of the inside of the fore shoes to prevent cutting: let these also be filed off, sloping towards the ground, though not so far as the heels.

An improved form of shoe, preferable to both the foregoing, has been recently introduced, which
is a near assimilation of the French and English shoes. Instead of adhering to the old practice of fullering the ground surface of the common English shoe, to admit of punching the nail holes therein, it is the improved practice to hollow that surface, and leave a shoulder towards the outer rim as a protection to the nail heads. This is performed by a tool resembling the head of a hammer, one face whereof is well represented by the annexed figure; the lower part (at a) being placed on the work, as is usual in fullering, but nearly a quarter of an inch from the edge; the hammer is applied (at b), which leaves (at a) the desired shoulder, and along that surface so far as nailing is necessary, a hollowness equal to the inner slope of the tool. This hollow is not in fact any more than a wider fuller, extending the width of the shoe, excepting the width of the rim left at the outer edge; though some do further prolong the hollowing unadvisedly all round the toe, and to within half an inch of the heel, whereby they leave a slight caulking that never incommodes the animal, but which may be increased in quantity and hardness towards winter. The operation of hollowing the ground surface just described produces a slight convexity upon the foot surface three-fourths of the shoe's width, leaving the outer fourth still flat to receive the bearing of the horn. This agrees tolerably well with Mr. Teast's plan; for hereby also the wall was pressed outwards, when it grew up to the convexity, and its expansion was
thus positively promoted. Hereby too the distance between the sole and the inner rim is increased, and is moreover less likely to retain stones, gravel, or filth, than is the usual flat surfaced shoe, and possesses all the advantages of the seated shoe of old Osmer, that has been claimed by some of our moderns. Moorcroft took great pains to recommend the seated shoe, but finding some difficulty in getting them manufactured, he set up a machine for punching out the hollows, that quite failed of success, because the power employed was only equal to cutting soft iron, and this was found inadequate to the required wear, we are told. Why he did not subsequently harden, or "steel" the toe and heels seems surprising at this day.

Healthy feet are those alone which we have kept in view hitherto; the bar-shoe, concave and seated shoes, being contrivances for ill-formed and diseased feet, require separate notice. But the idea of giving elasticity to the hoof by means of the jointed shoe, being a preventive remedy, calculated for the preservation of health by giving lateral action to the internal sensible parts of the foot, we will very briefly describe the contrivances of several inventors and patentees, whether philanthropic or sordid, with this previous intimation, viz. that it becomes "any and every" shoeing smith whatever to make "any or either" of such jointed shoes, notwithstanding certain "letters patent," letters of puff, or volumes of stuff, whereby those so-called patentees, and others, arrogate to themselves the
merit of being inventors, for the reasons set down higher up, page 492. Their patents are not worth a straw, unless for cutting into slips for tailors' measures. We must also here add the assurance of our belief, that this contrivance for affording expansion at the heels, by means of the joint, is the best antidote yet made known for correcting the evils arising from the application of a rigid iron defense to the horse's foot.

Objections have certainly been raised against this mode of forming shoes, that seem plausible enough at first glance: not so fast, however; for upon cool examination they vanish. The objectors aver, that because we cannot impart the desired freedom of expansion to the whole of the foot, forsooth, we are not to allow it at any part: if we cannot get all we want, we are to reject what is within our reach; all or none, say they, like froward children. One of these, who is likewise the last, tells us, "In order to admit of expansion and relaxation of the hoof by a joint, it would be necessary to make the nail holes wide enough to allow sufficient play between the shoe and the nails [!], thus producing an effect similar to the end play of carriage springs. But even supposing (says he) this provision were made, the shoe would soon tear out the nails."

To be sure it would, Mr. Goodwin (p. 187); but supposing (even or not even) that your shoes do not so "make play," no one would imagine that you were making game at your readers. Why, he
sets up a bug-aboo, and then knocks it down, with "I have often proved the truth of the preceding observations." But the observations being unjust, because applied to an unfounded suggestion, proof was not necessary.

The jointed shoe.—A form of shoe was propounded for cutting the shoe into three or more several parts; then lining the foot surface with leather, and fastening on the shoe in the usual manner, with nails that were inserted into each part. But this contrivance, though plausible, did not answer, inasmuch as the leather had not sufficient strength to stand the wear and tear. Mr. Rotch was the inventor of this notable affair, and took out a patent that, we may venture to affirm, will never be invaded.

Mr. Bracy Clark may have been the real inventor of the jointed shoe that bears his name, for aught we can tell, but he labours under the disadvantage of being preceded by about a century, by a French author; so that his battered saying, that his great discovery forms "a basis for the repose of the profession," however elegant in expression, becomes nonsense to our ears, who concede nothing to simple gentility, and less than that to self-complaisant egotism. "Clark's shoe," in its various modifications, differs nothing from the generality of shoes, except in being divided at the toe, and fastened again by means of a pin, screw, or rivet. The toe would be required to be made thicker than usual, let us suggest, to prevent the rivet's
parting, and to secure each head of it in a *counter sink*; one half the thickness of the toe is to be cut away on one side at the *ground surface*, and from the *foot surface* of the other half, resembling what is termed in carpentry a *mitre*; and these being brought close together, a hole is to be drilled or punched through both, and let the rivet employed be the size of the hole. Whatever degree of rigidity the workman might restore to the entire shoe, it is plain that the great weight of the horse would very soon strain the rivet, so as to cause it to relax therefrom, and allow the heels to expand by so much. That this might extend over a larger part of the front of the hoof, Mr. Clark preferred nailing the shoe pretty far back towards the quarters, which we reckon among the mistaken notions of the whole class of improvers. But mark the dissonance of our teachers! the next *inventor* or improver ran into the other extreme, erroneously punching and nailing up intolerably near to his rivets or *pins*, for he has two of them, as per marginal cut.

This representation of the shoe invented by Colonel Goldfinch exhibits a modification of 'Clark's patent.' Like it, the necessity of making the shoe thicker at the *toe* than usual with the ordinary shoes is evident. The patent was enrolled in October 1821, granted to Lieut.-Col. H. Goldfinch, of
Hythe, an exclusive right for fourteen years; and his specification of its advantages and novelty, and the manner of making it appears to be as follows: "The separation is to be made in any indented form, and the two parts fastened together with pins. It is further proposed to attach the shoe to the horse's hoof by driving the nails obliquely, as in the French manner of shoeing. With this view, the nail-holes are to be punched about one-third to half the width of the shoe distant from the outer edge, and tending in a slanting direction outwards." In this latter recommendation we cordially join the colonel: he was the first writer who noticed it, and is the mode of punching and nailing before alluded to, and hereafter minutely described as the only wise course. Since 1821 it was adopted by the more intelligent smiths of the metropolis. One main blunder which the colonel commits is evidently intended to correct the visible insecurity of his shoe at the joint: his nail-holes are punched so near his patent joint as to restore the rigid immobility the patent pretends to amend.

Coleman's patent shoe for giving pressure to the frog continues in use, notwithstanding the demonstrability of its inapplicability to frogs already diseased. But, in the hands of the professor himself, and any practitioner tolerably habile in his profession, we were free to allow, from the very first, it might be rendered available—but not in ordinary hands; with these it has failed of success—in some
cases from the want of an assortment adapted to the various kinds of feet; a defect that may be now remedied in some measure by the cheapness of the malleable invention of Mr. Dudley, as sold at a cheap rate by Mr. Long, of High Holborn.

Under these new circumstances, and seeing that Mr. Coleman's opinions as to frog-pressure, and the diseases consequent upon the absence of it, are embodied in his specification, drawn up to obtain this patent (for the professor has several), he may be allowed to speak for himself on this ever-interesting subject. He says, "the improvement proposed in this patent is to prevent contraction, and to relieve contracted feet, contracted frogs, flat soles, corns, sand-cracks, thrushes, canker, and quittors, and also to prevent cutting."

The patentee observes, that "the fore feet of horses in their natural state are nearly circular, but from the ordinary shoe worn in this country, which keeps the frogs from off the ground, the hoofs of horses with light fore-quarters are generally found to be more or less contracted, and this in proportion as the frogs are more elevated, and support little weight;" whence the cause of those diseases. To remedy this defect, and to afford the necessary expansion to the hoof, the patentee proposed the annexed forms, observing that no specific form of shoe can be suited to all horses under all circumstances, and to every sort of road; it being necessary to alter the shoes of the same horse at different periods.
The construction of the professor's shoe will be seen in figures 4, 5, 6.

"The bar of iron down the middle of the shoe, called the frog-bar, is made broader than the frog, and welded to the shoe. This bar, when the cleft of the frog is diseased, is slit open in the middle." But all that we have seen in use are without the slit represented in the cuts; and the welding on of the bar is greatly objectionable, inasmuch as the chief strain is at the junction of the bar with the shoe or tip, and we have often seen the bar break off here, or else by its lever force draw the nails, and throw the patent shoe altogether.

"When the ground is dry, the crust and sole strong, and the heels of the hoof high, the shoe should be made about an inch shorter than the ordinary shoe, as fig. 5, or shorter still, as fig. 6, with the hinder parts bevelled, but the heels of the frog-bar for contracted hoofs should not exceed the level of the heels of the crust or shoe." The patentee promised himself and the public great advantages from his contrivance, which we could never perceive it possessed; notwithstanding the public
or the military service, are said to approve of Mr. Coleman's patent; for they purchase good numbers, so 'tis said, of those which are cast of the new malleable metal spoken of at pages 503 and 514.

Of preparing the hoof.—The general principle of all shoeing is to support the foot off the ground by means of the wall or crust, and by this only; so that the frog shall not come in contact with the hard plain road, whilst it may be allowed to receive pressure upon going over soft ground: the first prevents injuries and resists wear and tear, the latter promotes the secretion of healthy horn, by reason of the proper degree of pressure that is to prevent this being received by the heel, frog, and bars. Whatever is here said, the fore foot is still kept in view, unless the hinder foot is particularly mentioned; and occasion will present itself for the distinction, as there is great difference in the wall and other external shape between the two, as regards heavy draught cattle. Greater heat, fever, and affections of the lungs also cause the fore feet to contract disorders unknown at the hind feet; whilst a tardy circulation of the blood, and the consequent relaxation of the animal system, to say nothing of the evils incurred by heavy drags against the collar, produce affections peculiar to the hind leg that are not known on the fore leg.

When very much flaky or rotten horn presents itself, the sole should then be pared the least, or not at all, for this is a proof that great heat, or inflammation, affects the whole sensible foot, and
also the hoof is then too brittle. When the flakiness is trivial, run over the whole surface with the knife, but go no deeper than the removal of the loose flakes. *La Fosse* and *Moorcroft* were both in the right, when they told us that paring the sole inconsiderately is "the chief cause of contraction;" for the sole is thus rendered less capable of resisting the pressure of the wall on all sides, and of the coffin-bone within, insomuch, that were the paring carried to an extreme, this bone would protrude at the sole, and come upon the ground for want of sufficient resistance. Whenever a smith applies his thumb to the sole, and then cuts again until he causes it to bend under the pressure, let him be admonished that he contributes his aid towards contraction of the foot, and some one or other disease of the sole. He has but to cut away a little more to arrive at the sensible sole, which would produce blood, and ruin the horse by a quicker mode than this thumbing and cutting, and cutting and thumbing comes to.

*The frog* seldom requires the knife; never after the removal of a shoe which has allowed it to come upon unpaved ground; for then the wearing away is carried on naturally; but if not so, the rough and rotten outside must be taken away, which some smiths effect by first tearing away the slips, or exfoliation, and then paring the mealy-looking part underneath. Hereupon the well recognised healthy horny frog makes its appearance, but is by no means to be meddled with. The cleft is to be
cleared out by means of a knife having a *sharp return* at the extremity; but it must be evident that if the cleft has incurred no foulness, nor the frog grown luxuriantly, neither the one nor the other will require the least reduction. We will not say a word on the necessity of removing the rotten overgrown horn at the toe, and round to the quarters, so as to obtain a proper seat or bearing upon the shoe, this being an affair within every one's compass; but the rasping should always proceed with the shoe lying before the workman's eyes, unless when he may find it necessary to take it to the fire for the purpose of making alterations. The habit of doing this to a nicety with a single heat may be acquired without going to the fire half a dozen times, as we see done; least of all should the shoe be tried on hot, that the most ignorant of workmen may see where it bears most, or the least industrious lessen his labour by softening the horn. Ruinous consequences attend the application of fire to the feet; and yet we remember the period when it was the common practice to place a shovel of hot coals on brittle hoof to ease the workman's labour!

When a foot is fitted to receive the shoe, the bottom resembles somewhat the hollow and rim of an oval dish. On being placed on a plane surface, the frog and heels bear equally; but when the shoe is applied, the frog is raised by as much as the thickness of the shoe may be at the heel. At the heels, for about an inch of its length, the *rim* of
the shoe is to project beyond the outside of the hoof, lest the growing state of the horn should cause the shoe to imbed itself at this part, where the substance is soft and the wear very little. Take good heed that the inner edge of the shoe-heel bear not on the ground more than the outer, but the contrary. The so-much-desired expansion of the heel may be promoted by making the heels thicker at the inner edge than at the outer, though this be but 1-32d part of an inch.

Nailing, a very important operation, requires much previous study of the formation and functions of the internal sensible parts of the foot, many injuries being inflicted by penetrating those parts to the quick, and thereby occasioning them to fester, as we shall see presently, when treating of the diseases incident to the sole. A good aphorism has it thus—"If it were possible to keep the shoe in position without nailing, we should then have arrived at perfection in the art of shoeing; it follows that the least number of nails that are driven consistent with safety, is the most commendable practice." It was Mr. Bracy Clark, in the plenitude of his many inventions, who once proposed to fasten on the shoe by enveloping the whole hoof in an iron defence, and fastening it by screws; but the scheme failed for a most obvious reason—its weight increased the offence adverted to elsewhere (page 488). But we will not speculate on novelties, nor further object, simply taking the evil of puncturation as one that is inevitable, though capable
of alleviation. All hands agree that the less nailing we could suffice with, the less chance there would be of driving into the quick; hence, the firmer each nail is driven, the less liable is the shoe of loosening, and this good never can be effected unless the nails fit the holes so nearly as to prevent shifting, and also pass through a good portion of the horn. Doubtless a couple of nails on each side would be sufficient to retain a light shoe for a short time, if the work be not heavy, and allow that desirable expansion of the heel which all agree promotes the secretion of new horn, and the health of the foot; but we employ double the number in common work, and seven altogether in the "improved shoe."

As before remarked, the fullering usually practised upon the common shoe is so near the edge, that the rim sometimes breaks off of high-tempered iron; whilst, if it be soft, the punching inevitably drives out a bulge that the smith seeks to reduce by hammering, which again contracts the size of the nail-holes: the latter error occasions the nails to break off in driving; the former leaves the heads exposed to be knocked off, or readily worn away; and, by either, the security of the shoe is diminished greatly and dangerously. Besides which objection to the old method of fullering, there is a corresponding necessity imposed upon the workman of clenching high up on the hoof, which increases the danger of puncturing the sensible internal parts of the foot. This entire objection to the narrow fuller, or groove, is fully remedied by adopting the pro-
posed manner of punching the nail-holes farther in from the edge, thus taking firm hold of the whole thickness of the horn, and driving out sooner and clenching lower than is ordinarily practised—say, \( \text{within} \frac{3}{4} \text{ of an inch of the shoe} \) in all cases.

The nail commonly used is much too long in the shank for any kind of shoe, and too thin near the head, but should be of the same thickness throughout from the head so far as the pointing takes place, for this evident reason, that the nail-head may fill up the whole of the nail-hole, solid. The material must be of the toughest quality, equal to Swedish, insomuch that the nail may bear bending forward and backward half a score times without breaking; it should have a counter-sink head to match with the second punch-holes, and the hammering which the head receives before, at, and after driving, sufficiently hardens it to resist the immediate effects of wear. Do not point the nails too much, lest they splinter in the driving, nor make two or three punctures before you drive home each nail: both these practices proclaim the clumsy workman.

Punching.—As before intimated, the nail-holes should be punched as far from the outer edge of the shoe as the wall is thick. A small punch of the size of the nail's shank is to be first driven smartly and visibly through, but not so deep as to raise a burr on the hoof side of the shoe. Then, open the hole with a pritchel; and a larger counter-sink punch, the size of the nail-head, is then to be employed, but not driven so deep as the small punch;
the first being of the size of the nail shank, the second is to receive a small part of the head. This mode is, of course, best adapted to the "improved shoe" recommended at page 497, where a shoulder and groove supply the place of fullering. But, in every form of shoe, and every modification of nailing, the manifest advantage of admitting the nail-head to a rest or protection from rude concussions against the ground, must be evident, when the counter-sink part of the head is allowed to lie deep in the shoe.

The number of nail holes has hitherto been eight, but a better practice prevails in some forges of driving seven nails only, three on the inside, four outside; whereby the fourth nail outside is thrown so much farther back than the third nail inside. More play is thus allowed for expansion at the quarters; and if the punching and driving be performed effectively, the hold thus obtained will be found fully adequate to any service to which the greater number of nails is applied. The safety of the shoe depends more upon the nails' passing through good sound horn, and filling up the punch-holes in the shoe, than upon their number. A good workman can hear when the nails thus tell, by the sound of driving. After punching, the smith must not apply heat, or a hammer to the shoe, with a view to reduce any bulge, or burr, which the punch may have occasioned; for this exploded practice spoils the shape and size of the holes, upon the fitness whereof wholly depends the
security of the shoe. Indeed, good and proper iron does not readily incur either of these objectionable forms, nor will it break or chip off at the fuller-edge (when such a plan is adopted) like ordinary metal.

*Driving* the nails *home* properly includes no small share of skill. Formerly, he who could drive highest into the crust without occasioning lameness was reckoned the best workman, whilst the *French method* of driving both into *sole and crust* is an error in the contrary extreme, and argues no little slovenliness and disregard of the construction of the sensible part of the foot. As may be seen and accounted for by reference to the section of a foot at page 443, *immediate* lameness is not always likely to succeed the pricking of the sensible part at *cc*, but matter may form underneath, and lameness ensue at a future day, unless upon removal of the nail it issue forth at once in the shape of blood. The hoof, which may have lost the elastic substance of this *sensible part* through age or infirmities, (at *ccc*) in the section just referred to, when *the wall* and coffin bone touch each other, then is the horse commonly "pricked to the quick" at once, and goes crippling away from the smithy.

According to the most improved modern mode of *punching* and *nailing*, the nail should enter at the conjunction, *nearly*, of the sole and crust, so as to penetrate the *whole* thickness of the crust, (as shown in the *figure* of Goldfinch's shoe, at page 501,) and be driven slanting outwards, so that the
clinch be little more than half the usual distance above the shoe. If the nail-holes be punched too near each other, and the driving is performed by a workman who drives and draws his nails, and then peers into the punch-holes, then points his nail and drives again—however well his work may appear when put out of hand, he will but have prepared the hoof for fresh injuries at the next shoeing; after this treatment has been repeated often, portions of the hoof are apt to come away, and the smith is thus compelled to fasten on his defence by the toe, or at the quarters, and so produce fresh offence and incurable lameness.

Do not nick the hoof, as is too commonly practised, previous to turning the clenches; as most feet cannot afford to lose even this small modicum of their natural support, and even the stoutest foot ought not to be subjected to the loss of so much of its main strength. Neither rasp off the clinch, by way of finish, for the same reason, but hammer it down like the head of a rivet; which looks well, and makes a show in the eyes of a customer, who now believes, justly, that he has got something for his money.

Diseased feet stand in need of various modifications and alterations of the foregoing shoes, of which the form most opposed in principle is the Bar-shoe, which is well calculated to prevent that elastic healthy action so much insisted upon as ne-
cessary to the secretion of new horn. As elasticity is desirable in health, so is it injurious when disease has once commenced: then it is the bar-shoe keeps the sensible parts at rest.

*Concave-seated shoe*, for convex soles, when these cannot be reduced. This is nearly the same shoe as recommended above, with a different name, and the making whereof has been undertaken only by the best workmen, or with much reluctance. To obviate this difficulty, a very neat *cast iron* shoe (let not the reader smile) has been manufactured, as well as those of most other forms for diseased feet, which may be obtained of Mr. Long, the veterinary surgeons' instrument-maker in High Holborn, and of the "patentee," Mr. Dudley, of Soho Square.

*Cast iron shoes*, however, have been at length made of a metal that admits of being heated and altered to the deviations which the feet of every individual horse assumes, according to circumstances. The mode of accomplishing this, and the manner of hardening the toe, &c. are taught in a printed paper distributed by the vendors. Great quantities of the casted shoes have been supplied to the army, and may be made available to *the service* in times of great exigency—for, what evils do we not endure when warfare adds to our sufferings! But the well-known rigidity of this material, being at entire variance with all our notions and experience of elastic hoof, seems a bar to its general introduction for healthy feet. Again, for hard-
working horses that require frequent shoeing, but do not secrete a sufficiency of new horn, the evident fact that the nail-holes will constantly occur always at the same spot, affording no fresh hold for the nailing in sound horn, must operate as a great objection to the general employment of cast iron shoes for working cattle.

Notwithstanding the French method of punching has been spoken of in terms of approbation, and their mode of driving and clenching low is recommended to imitation, let it not be supposed that in other respects they make the best shoeing smiths in the world, but the contrary. Their general manner of shoeing is sad, slovenly work to look at; and this very excellence of theirs just spoken of, is more attributable to laziness than to design or plan. Even in the army they assign two men to placing the shoe, a lacquay holding the foot and bringing the tools, whilst le marechal himself hammers it on with much display; and the agricultural smiths follow the same system. The youths who are reared at their national schools (see page 11, Note) are taught nailing upon dead feet placed in a vice, from their earliest years; a mode of instruction we strenuously advise the imitation of, in this country.
CHAPTER V.

Diseases of the Foot.

When these cannot be traced distinctly to any specific cause, they are fairly attributable to ailment of the whole system dropping into the legs, and "fever in the feet" is decidedly so, in our opinion, when both feet are so afflicted. Therefore it was that we noticed this disease along with "strain of the tendons," to which we attribute its origin, as much as to other causes of general heat of the foot. Indeed the whole structure of the foot of the horse is so peculiarly curious that it almost deserves a separate study; but we must always keep in mind, whilst considering its ailments, that the great irritation kept up by its extreme action is readily communicable from the one to the other, so that we cannot intelligibly separate the leg from the foot, when speaking of the ailments of either, notwithstanding we have thought proper to begin this third book with the disorders that are situated higher up, and mean to close it with such as only make their appearance below.

But there remains still another distinction that may as well be drawn here, before we enter into other particulars, as to fore foot and hind foot. In all the little dissertations which we have ven-
tured upon in this book, and elsewhere, as to the structure of the foot, and all the dissections we have made from time to time, we have taken the fore leg and foot only, with one unimportant exception. We know not why this preference was made; we believe the custom to be general, but of very little importance. For, the hind foot, though a little smaller, with thinner horn at the toe, and somewhat more upright in form, corresponds exactly in all its parts with the fore one, until age and deformity comes on; the back sinew descending from the hough behind the pastern bones, until its insertion underneath the coffin-bone of the hind leg, in the same manner as before described, as pertaining to the knee and bones of the fore leg.

When we reflect upon this strict accordance between the structure of the fore foot and the hind, and then look over and lament the numerous disorders that the first is liable to, whilst the hinder one is comparatively free, it gives reason to pause. But without entering upon an elaborate investigation of this difference as to health, we come to the conclusion that we ought to attribute diseases of the feet, as we have already those of the body, to excessive heat of the vascular system, promoted by the great exertions the animal is put to, and the rude concussions the fore feet in particular endure at every step, thus creating heat and attracting hither any evil humours that may afflict the body generally. In the manege, 'tis true, and on some other occasions of great shew, horses are brought
upon their haunches and curvet, or perform the demi volt, the hind legs come upon the ground severely, but this cannot interfere with the general rule.

**Fever in the Foot**

Is that low state of the symptoms which arises from a slight attack which has been neglected.

**Cure.**—Rest is indispensable; foment the entire foot with warm bran-water, or make the whole into a poultice sufficient to envelope the foot all over, as high as the inflammation may extend, which is sometimes as far up as the fetlock. Apply a cataplasm of fuller's earth, or of mashed turnips, alternately with the other remedies. When the heat is greatest at the sole, and the fever extends no higher than the coronet, a stuffing of cow-dung will reduce the heat considerably: it may be secured by thin splinters of wood, and changed thrice the first day or two—once a day afterwards. Introduce a strong solution of nitre, and let it be strong, as you cannot employ much of it. Both legs should be stuffed at the sole, though the sound one (if one only be affected) does not require changing. Let the animal have a loose stall during any stage of strain, or disorder of the limbs. Look after his evacuations, and cause them to be regular; a simple fever (or inflammation) of the foot depending very often upon nothing more than one or other of these being stopped, which affects the whole animal system sometimes, to say nothing of a single limb.
FRUSH, OR THRUSH.

A running of matter at the cleft of the frog or frush, was formerly called "a running frush;" the moderns, however, write it "thrush." But, to frush, being old English for to break, to crack, or crush, like the cracking of walnuts, we have preferred that term before thrush.

Cause.—Depraved habit of body and disordered lungs always accompanying the appearance of a frush, we have no hesitation in ascribing its origin to that cause, especially as it is proved to be a deep-seated morbid accumulation; aided more immediately, probably, by an injury received whilst travelling, either by the bruise of a stone, or the insertion of gravel at the parts. This latter, however, is not a necessary cause of frush, though the gravel and dirt work into the ulcer as soon as it opens; for the lurking approach of the disease towards this consummate symptom may be ascertained by turning up the hoof and pressing: the cleft, which will give pain and occasion the animal to flinch: inflammation has already begun at the insertion of the back sinew in the bottom of the coffin-bone, where the branches of the crural artery also enter the bone, at the bottom whereof is the sensible sole, which separates that bone from the horny sole. See this structure of the foot described at page 445, &c. Filthy stables promote frush, and, when the cure may be nearly effected, they cause relapse in nine cases out of ten.
Symptoms.—The earliest, as just said, is denoted by tenderness at the cleft of the fore foot, accompanied by sharp, quickened and irregular pulse, as usual in all cases of local inflammation, being at the same time both cause and effect. Of course it follows, that as the disorder in the sensible frog proceeds towards maturity, the blood feels and tells of that fact by increased disorder of the pulsation. These timely indications being neglected, as usually happens, if the animal be put along over stony or newly-dressed roads, the first discovered symptom will then be his tumbling down through acute pain. The cleft opens, and an issue of a most offensive kind presents itself.

Cure.—If not speedily taken in hand, canker will be the consequence of a neglected frush. But, as scarcely one in ten will take the precaution to ascertain, from the state of his pulse, when the horse is likely to acquire this or any other inflammatory disease, it may be deemed impertinent in us to say, that the preventive of frush in its worst state may be found in purging physic and a cooling regimen, as prescribed for general inflammatory and febrile complaints, set down at the commencement of Book II. pages 171, 182, &c.; for this disease frequently depends on some untimely-suppressed evacuation, as the urine, stool, or perspiration; then let these be restored by giving the diaphoretic powders, purging or pissing balls, according to circumstances. A very much hurried pulse would of course point out the necessity of im-
mediate bleeding; for the animal so suffering in the vital function must necessarily contract disease of some kind or other; and that particular organ, or member, which may be least able to bear it, is sure to feel its effects soonest. This is as likely to happen to a horse with defective frog, as to its size, texture, or shape, as to any other part of him. Then, let the careful owner examine and find out the least perfect part of his horse, let him watch it closely in all its weakness, and endeavour to detect the first symptoms of illness, that he may aid nature and restore her functions, before these run riot beyond the help of art.

When the frog has been pared away, and the filth of the sore removed, wash it with a solution of vitriolated copper, and apply a pleget dipped in tar or turpentine at the opening. If the case be a bad one, the wash may be made stronger by the addition of a few drops of vitriolic acid to the solution; and the tar may be poured into the opening whilst warm. Place dry tow and keep it in position by means of splints. Repeat this tar-dressing every other day, until the injured parts slough off. Purging physic will be necessary to complete the cure.

CANKER,

Evidently a corruption of the word cancer, as applied to a running sore in human ailments, it is yet well silently to permit the innovation, the better to keep the two practices separate, in small as well as more extended affairs.
Cure of Canker.

[Book III.

Causes.—Precisely similar to those which produce the frush, only making its appearance at the hind foot, and depending upon ill cured inflammation of the intestines, to diseases of the urinary organs, protracted, and greater aggravation. Our French neighbours write of the two under the same head, of cancer, let them be seated wheresoever they may.

*The symptoms* are those of frush, extended also to the bars of the frog, the heel, the sole, &c.; and so is the

*Cure*; with this addition, that the paring must be carried on to the extremity, baring all the diseased parts, though these extend over the whole bottom of the foot. Cut away the proud flesh to the quick, and when it has bled a little, apply

*The Powder.*

Sulphate of copper, 1 ounce,
Corrosive sublimate, 4 drachms,
Prepared chalk, 1 ounce.

Mix, and sprinkle a small portion of it over the exposed surface. If the disease makes a hollow between the hoof and the coffin-bone, the powder must be introduced there by means of a spatula, or flat piece of wood, with a bit of tow on it; but do not leave the tow behind, as that might produce a fresh disorder. *Butter of antimony* is preferred by some to the foregoing powder, because it is a liquid and acts more generally; but it operates only for a very short time before its effects cease, being
killed by the moisture of the disease it was meant to destroy. Bind up the foot until the following day, when the application must be repeated, after wiping away roughly the sloughing of the diseased parts.

As it is found of some importance to the cure, that the foot should be kept as much as possible from wet and filth, and seeing that the mode of tying on a great bundle of tow in cloth, in the manner commonly in vogue, often fails, a light shoe, adapted to the present shape of the foot, should be put on, for the purpose of sustaining the dressings, &c. which it may be found necessary to apply. The shoe has another advantage over the tying fashion, inasmuch as it allows of the animal to place his foot fairly on the ground, a position that mainly conduces to the cure by promoting the secretions, more especially when at length he can move about. Let the shoe be narrow-webbed, with a groove on the inside edge, so as to admit of a tin slider being shoved in and drawn out, when you desire to examine the under surface of the foot, to change the dressings, &c. Such a shoe will obviate the complaints usually raised by our stable attendants, that they cannot keep on the dressings, nor preserve the foot from damp, which always retards the cure; for they are most of them bunglers at bandaging, owing to the very little practice which falls to the share of any one person among the whole fraternity. Splents of wood may supply the place of tin, when this latter may not be at hand.
 Whenever the cankered parts slough off, and leave a more healthy appearance, the powder need no longer be applied at those particular places. Upon these lay on a dressing of tar, in which has been introduced about a tenth part of blue stone, powdered. Let moderate pressure be given to the sole as can be contrived, to prevent the granulation of new flesh coming on too luxuriantly, which is otherwise very likely to happen, on the edges of the wound particularly. In this respect, the grooved shoe will be found effectually serviceable. If, notwithstanding all your care, the edges will grow too fast, touch that part with lunar caustic; and in case the horny substance grows over the still cankered parts, it must be again pared away and laid bare. Perhaps the animal is young and vigorous in other respects, and his system probably would promote the secretion of new horn quicker than an older, or less healthy horse; this difference should teach us to employ some digestive for the dressings, which has less tendency to promote the growth of new horn than tar has, which would be found more proper for old horses. For the younger animals, let turpentine be substituted, into which has been mixed a small portion of the same vitriolated copper, (blue stone.)

From what has been said, the reader will perceive the dressings require changing with some degree of judgment and discrimination, and that they should not be passed over or delayed, as he values the horse; for, upon this marked attention
alone depends the cure, and such a cure as shall prevent a relapse. Of course, he will not fail to take care of the evacuations, as in case of *fulush*; nor that the earliest exercise the animal takes be proportioned to the amount of disease he has undergone in an inverse ratio.

**Prevention.**—As we have seen that inflammation is the immediate cause of all disorders of this class, and seeing that the irritation which produces this has been brought on by distress of the parts for want of due pressure on the frog, any one whose eyes are open may see the necessity of paring down the heels so that the frog may have a bearing, whenever the horse is walked over field or turf, for example. For hereby it will be seen, on turning to the brief description we thought proper to give at the beginning of this *Book*, pages 443 to 451, of the internal conformation of the foot, that the healthy action of the parts upon each other is only to be kept up by the pressure of the sensible frog upon the juices, that abound to redundancy at the shuttle bone, so that these may be dispersed for the general resuscitation of the whole foot, and to make up the losses it sustains by wear and tear.

"When the frog is not sufficiently pressed upon, (says Mr. Coleman), it becomes soft from the accumulation of the fluid which it naturally secretes in great abundance from the fatty [elastic] substance, which lies immediately under the tendon." This view of the process tallies tolerably well with our own examination of the subject, at the pages just referred
to, and elsewhere; except that for fat, we have more appropriately termed it a "juicy elastic substance."

SAND-CRACK.

When suffered to continue, the cure is attended with great difficulty, and the disorder may therefore be divided into two stages or degrees, like many other affections of the horse. The name of sand-crack is derived from the worst of these states, when sand, gravel, or dirt, has got into the crack, which constitutes the disease.

Cause.—A blow on brittle hoof will occasion sand crack of a very bad sort, but the accompanying cause is the cessation of the function of supplying matter for forming new horn in the vessels leading from the coronet. This may arise from an external injury at the coronet, or severe treatment for some other disorder of the foot, as quittor, or frush, but oftener both are indebted to a heated state of the blood for their origin, and the function may be restored by physicking the animal, provided it does not dung at proper intervals. Slight cases have been removed by this means alone. As the hoof is always hot, one main cause of sand-crack is referred to heated roads, to travelling in deep, hot, sandy countries; scantiness of water, and removal out of a cold to a very hot climate, as from England to India (East or West,) are all known to cause the heat and brittleness which accompany sand-crack.
Symptoms.—A split or crack in the hoof, on the inside quarter of the fore foot, for the most part, but often on the front of it, down towards the toe, and occasionally on the outside, and also near the heel. Sometimes it appears on the hind foot, on the front of it, and prevails with us generally in hot weather. Sand-crack is either superficial and easily remedied, or deep and extensive, requiring much attention, and an operation or two in its different stages.

Cure.—It will be seen, that a slight crack may, by working the animal, become one of the worst species. Pare away the rotten parts, if such be found, and make a transverse incision across the upper part of the crack; wash out the sand or dirt, apply daily tincture of tar, with a pledget of tow, and give the horse rest. Bind round the hoof tight with listing, and stop up the sole with cow-dung, and this treatment will suffice in ordinary cases. But when the crack extends so high, that there is no room left for making this incision across, to stop the progress of the crack, the disorder has assumed its worst aspect: the edges of the crack internally now press upon the sensible part, or ligamentary substance that holds the coffin-bone and hoof together, and inflammation succeeds, if blood does not issue forth. If the crack affects the coronet, you may draw one side of it down to the quick about an inch with good effect, but no farther, as that would occasion the hoof to divide more readily. Rest, however, will restore ad-
hesion to the upper part of the crack, and when this has taken place extensively, the operation of cutting across, or of firing it across with one line only, may be performed with every prospect of success; for, as the hoof grows down, which it does from the coronet, this transverse artificial crack you have made intercepts the material for forming horn, on its inside, and thus contributes greatly to fill up the chasm below. To increase this supply of the horny material, let the coronet be anointed with a solution of tar and tallow and hog's lard daily, which should be extended to the horny part of the hoof.

Stopping has been mentioned as necessary to be adopted on the first or mildest attack, being very conducive to recovery of the lost function of secreting the proper horny material. This, of course, will be attended to in every other stage of the disorder, whereby moisture is applied to the dry brittle hoof, and conveyed to its most sensible part internally. On the uses and advantages of this simple remedy we took occasion to say a few words when speaking of frush at page 64, and recommending the application of a web-shoe grooved, as an excellent auxiliary to the cure, by keeping on such dressings as might be found necessary; and by allowing speedy removal, it will also save much time and labour to that description of persons who are seldom inclined to bestow too much of either. A number of other contrivances may be adopted to apply the same remedy—for affording cool moisture
to the hoof, the readiest of which is the leading him forth to a shaded place, and there tethering him up, where he might stand upon the natural sod, grass, clay, or soft ground, without a chance of running about to make the case worse, as would inevitably happen. In default of this convenience, a good substitute is the sponge boot, with bran poultice to cover the whole surface of the foot from toe to heel. In all cases remember to keep out the sand, gravel, or dirt, which is ever likely to insinuate itself and protract the cure; and, if not otherwise come-at-able, an opening must be made for that purpose by cutting down one side of the crack, as before recommended. Proud flesh will be found at this part of the opening, which must be dressed with a solution of blue vitriol.

If the crack be near the heel, merely thinning the horn and taking off that part which bears upon the shoe, will assist the cure; and whatever shoe may be put on, care should be taken to prevent the crack from bearing on it: the bar-shoe for heavy horses is esteemed indispensable, and some farriers apply it invariably. Others again fire the foot, from the upper half of the hoof, above the crack, to the fetlock joint. This is certainly decisive practice, as the hoof is renewed with new horny matter, being so supplied as to thrust off the old one; but all violent remedies should be avoided until the milder ones have been tried and failed, which will not be the case with those means we have recommended above.
Causes.—An entire series of disorders, as canker, sand-crack, corn, and founder, may be referred to the same original causes; namely, a heated or inflammatory state of the blood, which accident may concur to bring forward in one or other form, according to circumstances. We shall not repeat what is already said on the two first-mentioned appearances a few pages higher up, but merely add, that distortion and undue pressure on the sensible sole occasions that irritation which brings on inflammation at its edge, where the shuttle-bone, or heel-bone, presses down upon it at every step, and causes the utmost bending that the minute elasticity of the hoof allows of; but contraction of the heel, which accompanies hot, brittle, and in elastic hoofs, prevents its bending duly and truly, and lateral pressure upon the quarters follows. The sole being thus closely pent up, the circulation is obstructed in its passage to and from the cavity of the coffin-bone, and a deposite of blood, which soon becomes offensive matter, is the consequence. Bad shoeing, whereby the heels are pinched, also, when the ragged hoof is left, which may have contained particles of sand, will cause irritation, and end in corn, or figg; as will also the fault of making the shoe too short at the heel, so that the heel of the horse in time grows out over it.

Symptoms.—The mischief thus commenced within shows itself between the bar and the crust, or
wall of the hoof, in a foxy or dirty-red tumour, with greatly increased heat. Lameness, in a degree proportioned to the badness of the corn, is usually the first symptom that directs our attention to the sole. Figg is but another name for the same kind of corn when situated close to the bar of the frog, a little farther back in the hollow of the sole. Pain, very acute on the touch; or, when the horse treads on a hard substance, he issues a moan, or grunt: it is that sound in which his voice is aptly likened to the complaint of the human sufferer.

Cure.—Although oftentimes very troublesome, returning again and again when the farrier apprehends he has cured it radically, yet no affection is easier of a partial remedy, or effected by more ordinary means. Deceived by the name, perhaps, resembling the hard excrescence called a corn, on the human foot, they proceed at once to “pare the corn out to the quick, till the blood starts;” but they heedlessly put on the same shoe upon the same thick heel and hard hoof which first brought about the malady, and the lameness returns. Let the heel of the shoe be cut off on the side that is afflicted, or if both sides have corns, a bar shoe is recommended as giving pressure to the frog. The heels are then to be rasped away free from any contact with the shoe; if they are thick and hard, this will give them play—if thin and tender, they will thus be free from pressure. The thick heel is most commonly affected, and should be softened by an extensive poultice that is to cover the whole foot,
after the corn has been pared and treated with butter of antimony. Tar is then a very desirable application, or Friar's balsam; and if inflammation is again discovered, poultice the foot once more. Fire is applied by some, but the hoof is permanently injured by the actual cautery; and whatever good is achieved is thus counterbalanced by the evil. Vitriolic acid mixed, carefully, with tar, in the proportion of one-tenth of the former to nine-tenths of the latter, will promote the absorption upon which the cure depends.

But in some desperate bad cases, the matter has already formed within, most offensively, and discharges at the coronet by means of that curious process of nature which we described at a preceding page, as affording the coronet the material for forming new horn to supply the wear and tear of the hoof. Upon paring away the horny sole, which now becomes necessary, the offensive matter will be found to have spread itself underneath the sensible sole, which will ooze forth and give immediate relief to the coronet. Let so much of the horny sole as lies loose from the sensible sole be pared away, and a dressing of tar, or of Friar's balsam, be applied as before directed; and if inflammation is again discovered, apply a bread poultice; should the growth of horn be found too luxuriant, discontinue the tar.

**STRAIN OF THE COFFIN-JOINT.**

**Cause.**—As previously observed, lameness of
the foot does not consist in a strain of the joint within the hoof, but is referrible to general concussion of all the parts, and is rather a strain of the back sinew at its conjunction with the bottom of the coffin-bone. Inflammation and accelerated circulation follow, and numbness of the foot succeeds: these, if not remedied betimes, are followed by ossification of the tendon, of the ligament of the small pastern, and the cartilaginous process (at $f$), fig. 2, plate 2, also becomes bone. That the joint of the coffin-bone with the pastern-bone within the foot may be strained, is very probable; but no injury, blow, or concussion, can affect it, which does not at the same time affect all the component parts of the foot. Horses which have thin hoof and sole are most liable to this injury.

**Symptoms.**—Sudden lameness, that is always increasing, and has scarcely an intermission, without any appearance to account for it on the limb; and the persons who permit the horse to incur this disorder by their carelessness seldom have the candour to acknowledge that they know the cause to be a tread, a rolling stone or a stumble, and the doctor is left to "find it out." Almost every one imagines the lameness to reside higher up, as in the shoulder or the hip joint. Great heat and tenderness of the part soon come on; the latter symptom may be ascertained by striking the hoof in front with a key or small stone, when the animal will flinch considerably more than when the corresponding foot is struck in the same manner. When the horse would
stand at ease, he usually does so with his toe pointing forwards, so as to keep the pastern in a straight line with the leg, and thereby take off the tension or pressure upon the back sinew and ligaments: the inflammation shortly after reaches the upper part of the sinew, as may be ascertained by passing the hand down over it when the patient flinches.

Cure.—Blistering at the coronet and fetlock repeatedly will reduce the inflammation within. A poultice covering the whole foot also tends to the same effect, which will be further assisted by paring the sole, if it be not already too thin: reduce the frog also, and do the same for the corresponding foot.

Formerly they pared the toe tolerably close, and bled it there, by making a longitudinal incision: the usual application of tar, &c. then completed the cure. But this is an operation that is seldom performed with sufficient exactness, the incision being too often made unwisely deep, so that other diseases were thus generated at some future day. Others, again passed a seton through the heel to the hollow of the frog, taking care not to touch the sensible sole. A third set apply the actual cautery, which comes least recommended of either of the remedies just described; especially when we consider that the actual disease is very often mistaken for some other; a remark that implies how much caution should be used in first ascertaining the exact seat of the lameness, its cause and symptoms, ere we set about the cure by such violent means.
FOUNDER

Is a disorder, or rather a complication of disorders, of the fore feet. Some controversy has crept into our books of farriery lately, as to what really is founder: and whilst some would confine their consideration of the subject to the foot only, others follow the fashion of grooms, and ascribe the incurable lameness that has no visible specific cause, to an affection of the chest. Hence the "chest founder" of the stables, and the "body founder" of White. "Shoulder-shook" is a provincialism of the smithy, when the farrier can perceive "nothing amiss" with the feet—so far as he can see, feel, or understand. Surbating was another name given to the symptom we now recognise as founder, at a time when it was the practice to divide and subdivide every disorder under many useless and unmeaning appellations.

Cause.—Hard work, bad shoeing, age and illusage, either of which produce so many other disorders pertaining to the horse in his domesticated state, precede founder; for we never meet with it unless the animal has been so treated or kept, and we look upon it rather as a complication or effect of several diseases of the foot. Some of these, we have seen, are liable to be mistaken for others; therefore do they get maltreated, imperfectly cured, or retain the seeds of future diseases; and founder is the name given to that which is otherwise inscrutable, has no other origin, and is badly defined
by all writers and talkers upon the subject. Out of this dilemma we do not at present attempt to rescue it: we care not for terms, unless insomuch as they can assist us to unravel the character of a disorder. *Contracted heel* is the slow cause of most cases of founder, whereby the quarters press on the coffin and shuttle-bone, and thus prevent the action of the latter, which is very great at every step, and is thereby mainly conducive to the proper secretion of the horny material before spoken of pretty much at large. To "a chill" is generally attributed the immediate cause of founder; and indeed the poor animal which has suffered severely at the hands (or spurs) of his master is most open to acquire any ill which *chill* or cold may inflict. When this chill takes place, the attack is sudden and usually violent; but is oftener attributable to the compression of the wall upon its contents, or the assumption of crookedness, or twist at any part. This constitutes the *slow* attack, and appears at the toe where the wall and sole join.

Inflammation always attends the first symptom of founder, if it be not an immediate cause thereof, arising, we have no doubt, from the waste or destruction of the secretion marked (c) (c) in the cut at page 443. To this conclusion we come the more positively, by reason of the absence of those secretory vessels in the feet of old, foundered or otherwise diseased horses; which secretions were designed to furnish the material for forming new horn and giving elasticity to the tread.
But young horses sometimes, while breaking in, by the violence that is deemed necessary, are foun-dered by the rough-rider, through the rupture or forcing asunder of the connexion between the hoof and coffin-bone, just spoken of. In such cases, the animal being vigorous and the foot replete with juice, the coronet is greatly affected by its oozing out there, in its blood and lymph state. If youth and general good health should bring the animal through his sufferings, its feet will ever after bear external marks of the internal injury.

Symptoms.—Curved, wrinkled, or striated hoofs, ever attend those animals which have been so over strained in youth, appearing as if the horn had been carved or indented; which arises from the coronet furnishing the horny material too luxuriantly, before it has received sufficient concoction within the coffin-bone, as before described, at page 449. Lameness in one or both fore-feet, with evident pain, and great heat in the whole foot, attend founder in every case. At the first attack of acute or violent founder, the horse is observed very restless in his fore feet, which he endeavours to ease, by alternately changing position, and lying down when he should be feeding. He brings his hind legs far under his belly for the same purpose, and if he is roused by hunger or mandate he lies down again. Considerable alteration takes place in the pulse, which indicates fever, and the patient breathes short with pain. The progress of these symptoms is very rapid, seldom occupying more.
than a day or two. Its appearance in the most decided form is at the junction of the crust and sole.

The slower or chronic founder begins with apparently rheumatic pains and awkwardness of going, for which he usually receives the whip. After a while, flattening sometimes appears on the front of the hoof, and the heels contract: the older animals have now short, brittle, shining hoofs, with the small pastern bone deeper sunk than heretofore; the hollow of the sole is converted into the convex, or pumice foot, so that the animal can scarce find foot-hold on the ground, but will slip and slide about. He is then considered groggy, or grawgy, that is to say, "like a drunkard," and may last many years: this is really chest founder, and indeed the whole limb is usually affected up to the very chest, though chronic affections of the lungs, or consumption is also denominated chest founder.

Whether the attack be of the acute or the chronic kind, it dies if not relieved; for the coffin-bone becomes rotten, and the hoof is cast off without the possibility of ever being renovated. In some constitutions, nature lends its aid in critically raising a tumour at the coronet, the breaking whereof and the discharge of offensive matter effects a cure. The same sort of critical tumour as denoting the crisis of general fever, or inflammation, was noticed at page 319, "Critical Abscess."

**Remedy.**—As soon as discovered take off the shoe, note well the condition of the sole, the heat,
and other symptoms, for according as these vary, so must the remedies be changed. Draw the soles a little with the buttress if found too thick, not otherwise; rasp the heels and quarters, which will ease the pain occasioned by the binding of the hoof, and give room for the action of the foot; a fact that may be ascertained by bending it at the pastern, forwards and backwards, before the operation, and trying the same experiment afterwards. Apply a bran poultice warm to the whole foot daily, but do not add to it any greasy or oily substances, as is too often practised. The sponge boot may be employed with advantage, made large. After three or four days, that the horn has somewhat recovered its former consistency, put on the shoe gently, and walk the patient, to try in how much he is now lame: and if the attack has been a slight one, he may recover with very little more treatment than a turn out in a meadow will afford. Otherwise the feet must be stopped, and kept moist and cool, as directed in case of Canker at page 523.

In all cases, (except where the foot is pumiced, or the sole is very thin), the jointed shoe of B. Clark, or of H. Goldfinch (page 501), will be found serviceable, as being well calculated for giving play or action to the parts of the foot, which produce the secretion that is so salutary to the renovation of new hoof; but which the symptomatic disorder we call "binding of the hoof" has sadly perverted into an offensive and harmful matter.

The proper secretion of the juicy elastic sub-
stance, for the formation of new hoof, being essential to the restoration of the horse, and as the lameness will not wholly subside unless this process goes on healthily, resort must be had to blistering, provided he still goes lame. This application should extend from the coronet and quarters to the knee, and be repeated, taking care to keep the heels open and the sole stopped. The good effects to the sole that will be found to result from blistering shows the connexion or companionship that exists between the legs and feet, as we took occasion to observe at a former page.

But, as to drawing the sole, as before recommended generally, there is one exception: if the lameness and other symptoms come on after an inflammatory fever of the whole system, then we ought to look upon it as an effect of the fever seeking to throw off its dregs thus critically; and a swelling and discharge at the coronet may be expected soon to take place that should be encouraged, and treated as simple abscess, not fistulous. When this is the case, the bar-shoe is better adapted to keep the parts in position, that the discharge may proceed temperately.

In default of sending the sick horse to a meadow, he may be allowed to stand on a clay-made floor in an outhouse by day, or any slip of soft ground; but by no means adopt the plan of putting the patient upon litter that is damp, and therefore half rotten and heating. A number of contrivances for affording coolness and natural pressure to the sole
and frog, besides the foregoing, have been resorted to, and among these the admixture of vinegar, alegar, verjuice, or solution of nitre with the clay, with the *stopping*, &c. are well calculated to answer the purposes intended. Rubbing the knees with turpentine is also serviceable.

*Physic* would not of course be neglected at the earliest stage of lameness, adapted to the previous state of the patient’s bodily health, and calculated to lower the access of inflammation, which so much pain must naturally produce. Either of the three evacuations being suppressed, or imperfectly performed, must be restored, and a purgative, an urine-ball, or a diaphoretic powder be administered as occasion requires, and opportunity presents itself: of course, neither of those would be given while the animal is out of doors.
BOOK IV.

SEVERAL POINTS OF INFORMATION PROPER TO BE LEARNT.

CHAPTER I.

Precautions necessary to be observed on buying a horse.

Much as hath been said of the make, shape, and proportion of the various breeds of horses in (chap. i. book i.), some few precautionary hints, still more familiar, seem desirable in this place, if they be not specially called for, as necessary to the right application of the principles therein laid down. Of the several points of inquiry to which purchasers apply themselves, the age of the animal is ever considered the most deserving of attention; the state of its legs, bodily health, and eye-sight, coming next in order, if general appearance, built or structure, does not precede every other. On each of those heads we now offer a few words of advice, most of which are tolerably well recognized, though seldom put in print, as most of those who deal in horse-flesh acquire their knowledge from experience rather than books, and do business by a kind of rule of thumb. Before all things, the new horse-dealer should guard
against imposition, and not "look at a horse" where he has got to withstand two or three masked advisers—employed persons with the dress and address of gentlemen, who assume to be purchasers. To be sure, no one desirous of a nag would submit to the imposition of a cart-horse instead; but, next to this kind of gross attempt, the thorough-paced dealers practise deceit of every species, and throw obstacles in the way of cool examination, especially when we come to investigate the seat of any actual defect.

General appearance: an idea of a good horse.—And first, that we may make no blunders, and the younger portion of readers be thinking of one part of him, whilst we are talking of another, let the annexed plate of "Terms commonly made use of to denote the external parts of the horse," be kept constantly in sight, so that there be no mistake of that sort.

Previous to stating our own old English notion, it may not be useless to quote the instructions with which the purchasers of cavalry for the French military service travelled (as we believe) over that country. Its coincidence with our own opinions and practices is at least curious, though on such a topic no Englishman whatever requires instructions from a foreigner, if his own assertions are to be taken for genuine. "The person sent to purchase horses should not only keep in mind the colour, height, and price of horses for which he is to treat, but also the usual defects of the country, that he may guard against them: these are, faulty sight,
flat hoof, too brittle, or too soft, and affections of the lungs. Though he knows already where horsefairs are held, he should prefer travelling round the adjacent country, a short time previously thereto; as he may be sure that *all the good horses are sold before it begins*. The age should be between four and five years, and as little above as possible.

"Those things being well thought on, the purchaser will look at the horse sideways at a tolerable distance: he will choose him as nearly as possible one tenth longer than he is high, measuring from the breast to the quarter, and from the withers to the ground, so that if the horse be *five feet* high, his length should be *five feet* and a half.

"Preserving the same situation, he will see 1st, If the horse has a small head, not too fleshy, perfectly free from tumours, and *well placed*, neither carrying it too low nor too high; 2nd, If he has not an ill-shaped neck, with his windpipe hanging too low, or bending; 3rd, Whether his withers be either too sharp or too large, with fleshy shoulders; 4th, Whether he is not hollow backed; 5th, Whether his chest be well formed, neither too round nor too flat; 6th, Whether he be low-bellied, with a small sheath; 7th, Whether he be touched in the wind; 8th, If his forelegs are not too slender, or his *hock* do not bend forwards too much; 9th, If the tendons or back sinews be not ailing, *i. e.* either sore to the touch, or else stiff-jointed; 10th, Whether the animal be not either *long-jointed*, or short-jointed; 11th, Whether he
be strained in the pastern joint, going low; 12th, Whether flat-hoofed, with low heels; 13th, Whether he be not narrow at the hind quarters; 14th, Whether he has not spavin, windgall, or curb, ring bone, or thorough-pin, or is likely to cut. Examine his sole and heel for thrush, canker, or corn, and if contraction has taken place.”

Having thus before us the Frenchman’s precautions, we come to the Englishman’s long-accepted description of a good horse, and nothing else. His head ought to be lean, of good size, and long; his jowls thin and open; his ears small and pricked; or, if they be somewhat long, provided they stand upright like those of the fox, it is usually a sign of mettle and toughness. His forehead long and broad: not marefaced, but rising in the middle like that of a hare, the feather* being placed above the top of his eye, the contrary being thought by some to betoken approaching blindness. His eye full, large, and bright; his nostrils wide, and red within; for an open nostril betokens good wind. His mouth large, deep in the cleft, and hairy. His windpipe big, unconfined, and straight when he is reined in by the bridle, for, if it bends like a bow (or cock-throttled), it very much hinders the passage of his wind. His head must be so set upon his neck, that there should be a space felt between the neck and the jowl; for, to be bull-necked is uncomely to sight and prejudicial to the horse’s

* The feather is a natural frizzling or twist of the hairs.
wind. His crest should be firm, thin, and well-risen; his neck long and straight, yet not loose and pliant, which our north countrymen term withy cragged; his breast strong and broad; his chest deep at the girth, his body of good size and close ribbed up towards the stifle; his ribs round like unto a barrel, his fillets large, his quarters rather oval than broad, reaching well down to the gaskins. His hock bone upright, not bending; which some do term sickle-houghed, and think it denotes fastness and a laster. His legs should be clean, flat, and straight; his joints short, well knit, and upright, especially at the pastern and hoofs, with but little hair at his fetlock: his hoofs black, strong, and hollow, and rather long and narrow than big and flat. His mane and tail should be long and thin rather than very thick, which some think a mark of dullness.

Some do affect a small head at all hazards, thinking none other belongs to a good horse, but much will depend upon how it is set on; if that be upon a crane neck, as usually happens when very small, he will carry unsteady, with tail up as a counterbalance; and, if large head arise from thickness of the jowl, this will also be a real deformity and interfere with his safe going: hard mouthed usually accompanies the great big head at the jowl. Expanded forehead is quite a different thing, and belongs to neither of those objections, but on the contrary is a redeeming sign of good breeding for any kind of faulty head, or long or
short, or thick or thin. The crest being slightly curved is always accompanied by distinctly marked windpipe. No horse with a bad shoulder can carry his rider with ease and pleasure on the road, though a large one be requisite for harness, or a very oblique one belong to a speedy horse; because it is the hind legs that send the animal along, as was eminently the case with Eclipse. See pages 26, 38—60, of Book I., where many other points to our present purpose are discussed.

As to bodily health, also, the reader will not have far to look to enable himself to judge how any animal is affected which he may desire to purchase. The whole volume now in his hands is devoted to a perspicacious description of the functions of animal life, and of their derangement. As to his wind, the reader will turn to page 98, &c.

AGE.

General appearance bespeaks the age of every animal, to those who have much practice in ascertaining that point, and whose interest may be said to sharpen their judgment: in the horse we are enabled to make a fair estimate of his years from the birth, to nearly twenty, by means of its teeth, but then we should guard ourselves against a number of deceptious tricks that are practised on the unwary.

A certain juvenility of countenance and springiness of action, legs long compared to the carcass,
or filling up, large at the knees and other joints, wide jowl, rough coat, and intractability, denote the foal and colt in succession; all which indications vanish gradually as it advances towards maturity, and becomes full mouthed. Heavy cattle assume premature age and sometimes deceive us upon the first view; nor do such decay when aged so fast as the more spirited, fretful, and lighter breeds: and as no one would purchase a horse for use before it be fit for his purpose, nor take to one that is worn out, the vendor hesitates not to stretch a year or so, one way or the other, as may best suit his own interest and his customers' wants. To aid their nefarious designs, they are said to file the marks of age in colts' teeth, and to bishop the aged, for confirmation of their falsehoods. But we never rely wholly upon those marks, but turn our attention to the curve of the tushes in the horse's mouth, and the sloping forward of the corner teeth in both sexes, to detect the imposture.

When we open the mouth of a full grown, or four year old horse, we perceive twelve nipper teeth in front and twenty-four grinders behind: between the two sets, above and below, a space is seen on the gum, designed by nature to receive the bit, and termed the bars of the upper or lower jaw, as the case may be. About an inch behind the last of the front teeth, the male has tushes at this age, which seldom occur with mares. The tushes coming up in the lower jaw sometimes occasions soreness at the bars, when these are to be
balanced and the tushes appear: this the dealers effect prematurely at times; and having also drawn out the two front sucking teeth, this causes the “horse teeth” to come up soon, so that the animal may appear *four years old* before its time. Pursuing the same species of deception, they proceed to draw the remaining sucking teeth, that the animal may assume the appearance of a *five year old*. Jockies have then a pass word for this operation, which they term “all up!”

In examining the mouth to ascertain the age, we leave entirely out of consideration the grinding teeth, and chiefly rely upon the under jaw; though when deception may be suspected, the buyer should refer to the upper teeth also, as these follow the same *course of nature* as the lower, but do not decay so fast in old age.

At *fifteen days* old the fore teeth (two above and two below), appear above the gums, the outside shell *first*, having muscular substance in the middle of the two shells, which fills gradually up, till about the end of the first year, when the surface becomes smooth, and a small ring is observable towards the root of each.

Meantime, when the foal is a *month* old, the next two teeth (one on each side) above and below, appear in like manner; and at thirteen months the fleshy cavities of these fill up, and a ring is observable as in the former.

At four months old the *corner teeth* come up, and the filling up is similarly effected at sixteen or
seventeen months old. After this period the whole six teeth wear even, and so continue smooth and unmarked until two years and a half, the corner teeth being still the least perfect, the front ones largest.

During this state of the mouth, if the unprincipled dealer would give his animal's teeth the mark of three or four years old, he is said to "file" two or four front teeth hollow in the middle; though in fact it is burnt in with an acid that is capable of destroying the hardest substances. But this falsification may be detected, 1st, by comparing the upper with the lower jaw, which they omit "to file;" 2nd, by noticing whether the marked teeth have the ring before described, as pertaining to the sucking teeth, but does not belong to the horse teeth—lastly, these latter are larger, of a brownish yellow tinge, and soon acquire tartar, very unlike the fine whiteness of the sucking teeth.

On rising three years old, the two fore teeth (below, and two above) fall out and are replaced by two horse teeth, having the hollow mark in the middle, as shown in the

* Cut by Mr. James Lee from drawings by Newton Fielding, Esq.
annexed cut. As just said, they are also larger and of a darker colour than the sucking teeth. But between the third and fourth years, two further colt's teeth (as well above as below) shed, and are replaced by "horse teeth," i.e. larger and browner than the sucking teeth, with the black mark; the tushes also push forth, and the horse is now full mouthed, as represented by the cut in the margin.

Only the corners now remain unchanged from colts' to horses' teeth. These differ from the others in being shorter, smaller, and of a shell-like appearance, until the middle of the fifth year, when these also are displaced by horse teeth, in shape much like the former, and their marks but just perceptible within the upper surface. But, toward the completion of five years of age, they become larger, are more strongly marked, and are grooved on the inside, which groove denotes the age to be five with precision; no deception can be practised on this point, nor as regards the tushes, which are now curved, having
grooves inside, that may be felt with the finger, and seen as represented in the figure annexed. At this age the two front teeth give proof of being worn, principally on the outer edge; the wearing away goes on, and at *six years* the surface is level, or as they say "the mark is gone," whilst the next two teeth also begin to wear. Now, also, the *grooves* just spoken of in the corner teeth fill up; the curve in the tushes is diminished, and at *seven years* their grooves fill up in like manner, and become convexed in another year or two. Up to this age only the two corner teeth retain the *mark*, and that but slightly; when the horse acquires the term "aged," and these two, likewise, soon after become smooth.

This is the state of the *lower jaw* at seven years old, but the teeth of the upper jaw do not fill up so fast by two years; so that a tolerably shrewd guess at the age of a horse may be formed until it is twelve. The *marks* in the two front teeth of the upper jaw are not obliterated until eight years old, and the next two become smooth only at the tenth year of its age; being each two years later than happens to the corresponding teeth of the lower jaw; whilst the two corner teeth *above* do not lose their marks until the twelfth year.
The tushes of old horses, then, have neither curve nor groove: they wear away at the points as if they had been broken off and polished again; the corner teeth appear long and leaning forward; the upper teeth project over the lower, and all lose their oblong shape, whilst the gum recedes and leaves their roots bare, so that the teeth seem as if grown larger. When the teeth do not so meet evenly, certain dealers file away the projecting teeth; for this denotation of old age, which may be attributed to a strong mouth, sometimes happens prematurely without any other corresponding sign. In two or three other respects we notice similar deviations from the general rule, that none know how to account for, unless it be that such animals were got by old parents, when the hollowness over the eyes, also, will be found to disfigure young colts of the most tender age. Some, again, lose the mark in all their teeth except the corners, as early as five years old; others have hard mouths and the bars almost callous; but all these have the hollow just spoken of. This defect dealers endeavour to rectify by puncturing the skin and blowing it up. On the other hand, some horses are so strong in the mouth, or rather healthy, that the marks of five years old are retained by them until six or seven.

Extreme old age may be further ascertained by the mouth, with moderate accuracy. Up to ten or eleven years old, the teeth generally retain their oblong figure and touch each other. From this period the teeth contract in size, become roundish,
and leave a small space between them; which space increases up to the fourteenth or fifteenth year, when each tooth assumes an angular shape, and projects forward, irregularly. In another year or two the under lip hangs down, the jaw becomes neaped and contracted, the gum recedes considerably from the roots, and the shape of the teeth is then of an oblong, but directly contrary to the first.

Moreover, the eyes of a horse approaching twenty years wax yellowish, he winks much, and the inner skin of his mouth turns outward. If naturally of a grey or roan colour, the darker spots turn rusty, and he is then what they term "flea-bitten:" gradually he turns grey, beginning with the head and finishing with the legs.

LAMENESS

Is not easy of detection, when the horse comes from the hands of a dealer; who of course makes the best of him, and endeavours to inveigle our judgment, and to throw obstacles in the way of examination. Perhaps, when a horse walks queerly, or unaccountably odd, this should be sufficient cause for rejection; but, if he suits the purchaser's purpose in other respects, we are usually induced to look at him a little further, and this is the reason that the seller always puts his tit upon the pace he can perform best, commonly the gallop. All paces are natural ones, except backing and cantering,
and are all modifications of the walk, trot, and gallop. The walk is made in four equal steps; the trot in two, and the gallop likewise in two, except at setting off. When the steps are not made in equal time, then is the horse lame. This is observable when he walks, is more apparent when he trots, but is scarcely perceptible when he gallops: therefore to judge whether a horse be lame or not, he should be put upon the short trot, because at the long trot it is more difficult to be discovered by seeing him go, than by hearing the difference of sound in each alternate step. Hence, it will be seen, we must examine whether a horse be lame by a gentle trot. To judge whether the lameness be before, let him come towards you, then the fore leg which falls to the ground the quickest is the sound leg, and the contrary one is faulty; but to find out whether the inequality of his paces proceeds from defect in the hind leg, make him trot from you, and that leg which is longest in coming to the ground is affected in some manner or other; and in either case the faulty leg is to be closely examined, according to the instructions before set down, page 458. Even then, unless the person has great experience he is liable to be imposed on, as the poor animal is often lamed of a fore and a hind leg at the same time: an occurrence that may have been inflicted on one leg in order to counteract the first appearance of actual lameness in the other. To detect this cruel imposition, it becomes necessary to examine every leg, to turn up all the

b b 2
soles, and to ascertain whether the horse has not been pegged between the shoe and the sole, or his "heels opened," by the shoeing smith for the purpose of sale. See Index for lameness.

EYE-SIGHT.

Acute pain affects the eye by contracting it. Thus founder, corn, &c. occasions one eye to be less than the other; and the sympathy that exists between the stomach and the eyes, has the same effect on both when the organs of digestion suffer pain. Small eyes, however, is more frequently an original hereditary defect, and are objectionable, inasmuch as the horse requires to see before him without turning his head, which he cannot do unless the eye-ball fill the socket; to say nothing of the known predisposition of such eyes to contract disease.

They of the stable term this "buckee," or buck-eyed, though with a very poor taste for natural history; the buck's eye, whether of deer or coney, being large. Very large eyes are equally undesirable; for such horses see too much, are apt to shy, and are also more liable to contract disorders than those of a middling size. A handsome eye is strong, well placed in its socket, not projecting beyond the eye-lids; the cornea should be transparent, and show distinctly the various humours of which it is composed.

No animal is so subject to blindness as the horse. This arises from the great heat of his blood, and
the constant feverish state in which his great exertions keep him, which occasions inflammation, and thickening of the extremely thin membrane that covers the eye. To discover when this misfortune has commenced, place the horse within the stable door, or under a pent-house looking outwards; then get behind the head and look sideways through the eye towards the light, whereby you ascertain whether it be clear and transparent as it ought, or whether any specks are discoverable, that denote the coming on of a cataract, or perhaps an ill-cured opacity of the vitreous humours. Now bring the horse’s head to the stable door, and placing yourself opposite him, in that situation examine all the parts, as well the crystalline lens in the centre, as the uvea, and the haw, of the eye. Whenever any speck, or inequality is perceptible, look closer to discover precisely what part is affected. The most common defect is one of original construction, and consists of round projections of the ball, chiefly on the lower edge of the uvea or iris. In this situation they are of no actual disservice; but on the other hand become very much so when found on the crystalline lens; for the uvea being capable of expansion and dilatation, these spots appear and disappear before the animal’s sight, and cause skittishness.

Blear eyes, caused by a thickening of the aqueous humour or tears, is termed “moon-eyed,” from its increase with the moon; this moreover decreases with the changes of the moon, and is
capable of cure by treatment as for a cold in the nostril, where the superabundance of this watery secretion naturally escapes by *two duets*, that are not unfrequently mistaken for glandulous chancres. Not so, however, with a thickening of the crystalline humour, which causes *cataract* and another disorder still more dangerous, which attacks horses that have the best of eyes, and is called *gutta serena*. When these exist the horse does not see well, as may be discovered by his walk; by his lifting his fore legs very high, and carrying his ears alternately one before and the other behind.

---

**CHAPTER II.**

**Blood-Letting.**

Every one, almost, can bleed a horse in some way or other, and it is often found extremely desirable that the operation should be performed without delay. But, like many other excellent remedies in the hands of unreflecting persons, this one is frequently employed imperfectly, as well as too often. Each has his peculiar notions, either as to the fit *part* whence the blood should be taken, the *time* when it becomes necessary, or the *quantity* proper to be taken; the latter being the more common error, as it is also the more excusable, in-
asmuch as they can plead "authority" either way for what they do, is nevertheless demonstrably ruled by wrong principles. The practice of bleeding at given periods, be the quantity taken ever so small, is most injudicious, to say no worse of it; for why should we employ a curative when there is nothing to cure? especially when we thereby subtract from vitality itself.

"Only bleed in cases of inflammation," say the French farriers, and then they take a large quantity, under the impression that taking a quart, or little more, from a mass of two hundred and twenty quarts, which is fairly calculated to reside in a middling-sized horse, "is but trifling with the disorder." The existence of inflammation, or fever, is to be ascertained by the state of the pulse, upon which we were tolerably minute whilst speaking of fever, &c. (See Index), the number of beats, and the kind of vibrations, being well considered, previously to taking the fleam in hand, when the quantity drawn should be commensurate to the extent of the disorder. Keep in mind, however, the exceeding danger of mistaking one series of febrile symptoms for another, as may be judged of by turning to those of "low fever," at page 171, when bleeding would destroy the horse. See also pages 180, 187. Without question, if the operator entertains a doubt about the symptoms as indicated by the pulse, the least quantity he takes is likely to perpetrate the smallest amount of harm; whilst, if he be correct in his observations, and has witnessed
the good effect of bleeding in strictly similar cases, its inadequacy can effect no good whatever, nor repetition amend the matter one tittle, but the contrary. So that he must be wrong either way.

For, as was proved at the pages before referred to, the disorders for which bleeding is found serviceable, depend less upon the quantity of blood that may be in the system at the time of the attack, than upon the construction or "state of the blood," and the degree of irritation that may exist in the vessels that contain it; both which affections, or causes of disease, are more frequently to be moved by the manner of taking any given quantity than by the actual weight, or rather the measure thereof. If the blood, for example, be drawn from a small orifice, no matter how rightly judged the quantity may be, however consonant to the proportions before prescribed at page 183, yet the irritation of the blood-vessels, known by the rigid feel of the artery, will not be reduced, nor the animal recover. "He has been bled," is thrown in the face of the doctor, "and is no better: we have even preserved the blood." But the thing has not been performed with requisite skill. Among other absurdities, the operator will perceive the impropriety of permitting the blood to escape upon the ground, and then guessing at the quantity drawn; than which no practice can be more slovenly and fallacious.

A measure should be provided, marked with

* That is to say, the proportions of its then component parts, which is mainly affected by disease.
graduated circular lines, and numbered from the bottom by pints each. Glass forms the neatest vessel; but pewter offers a less brittle material in horse medicine. The blood should be preserved awhile in the vessel, that the form it assumes in coagulating may be noted and remarked upon; as commonly happens most indiscreetly by all by-standers, whether it be caught or not; for very few can pronounce accurately, upon the view, the quantity of disease the blood indicates, particularly when it is on the ground; nor yet when in a vessel, unless it be caught properly.

Let the vessel be presented so as to catch the blood fairly, and not be permitted to trickle down the sides, whereby the manner of its coagulation is affected. Blood that is drawn from a healthy horse soon congeals in nearly one uniform mass, about one fifth of water only remaining at the top; from the residue you may wash away the red or colouring particles, and leave a pale thick coagulum or lymph. In a pound of such blood will be found these proportions—viz. 8 ounces of thick lymph, 5 ounces of the red or colouring particles, 3 ounces watery. If the operator keep stirring the blood until it cools, the water does not separate, but the whole forms one homogeneous mass. In cases of great inflammation or fever, the watery proportion is much less, and the blood is then consequently more viscid or thick; which proves that this viscidity is an accompanying symptom of the disorder, as maintained in various parts of this volume; but, as the fever
goes on, the animal loses appetite, and he makes no more new blood; the blood then becomes thinner in consequence of the deposit of lymph made in its circulation, and the red part predominates. On the contrary, in low fever and all languishing disorders of a tardy circulation, in cases of edematous tumour, the watery part is found in the greatest proportion, and the red part is then almost extinct; in inflammatory fever the red particles predominate, the water is nearly dried up, and the lymph greatly decreases.

**Instruments.** The fleam and blood stick have been attacked as remnants of the old school, but were unjustly stigmatized as a rude method of obtaining blood. In the hands of judicious persons, the fleam has been found equal to every purpose that was required, and when used adroitly no other means of blood-letting, probably, ever will supersede it. But during the rage for improvements and new inventions, that prevailed a few years since, they sought to avoid a certain clumsiness of its application by introducing the lancet to general use. True it is, that the awkward method of making two or three aims with the stick, before striking at the fleam, occasions the horse to shy, especially whilst every vessel of the head was swelling with blood, in consequence of the application of the ligature round the neck; and equally true, that careless operators frequently cut through the vein, so as to cause subsequent disorders; whilst others, again, dangerously wounded the carotid
artery that passes under the vein; yet are there insurmountable obstacles to the general use of the lancet, that never can be overcome.

Of those, we need mention but one objection, viz. the time occupied in making the opening—seldom less than four or five seconds, which causes the animal to move its head, and thus to defeat the intention of making a sufficient orifice, whereby the adipose membrane of fleshy animals is allowed to interpose, and the blood trickles down the neck, and part of it gets underneath the skin. By the way, this happens when the operator does not bleed sufficiently high up the neck, the skin and muscle being much thicker lower down. Upon large animals, likewise, the lancet is wholly incompetent to its purpose, owing to the very thick teguments it has to pass through, leaving entirely out of consideration the substance of the vein itself. To remedy those objections, the spring fleam is more advisedly employed by less practised hands, and is found to combine the advantages assumed for the lancet, whilst it secures the requisite orifice punctured by the fleam.

**Bleeding** is now performed without previously applying a ligature, as it became apparent that the blood which was thus detained in both veins, distended also the capillary vessels in the head, which then press upon the brain. Hence it frequently happened that vertigo came over the animal, filling it with the apprehension of danger. Sometimes it fell down through compression of the brain, and
plunged; whereupon the disconcerted operator was known to give it up for a bad job, at the moment it became more than ever necessary, charging the fault to account of the horse's restiveness, with an expressed intention of resuming the attempt at some more favourable opportunity. But this was a promise he was seldom able to redeem cleverly; the alarm excited by striking the fleam again and again scarcely ever subsiding, for the tension of the vein would but increase with the continuance of the ligature, and cause it to slip aside more certainly. Apoplexy and death has ensued from the same cause, namely, the application of a ligature, and the consequent bursting of the fine blood vessels of the brain.

A large vein is more desirable to take blood from, as an evacuation that is to relieve the whole system, than a small one, and the jugular or neck vein, within a hand of the jowl, is ever preferable; because the smaller do not conveniently admit of making so large an orifice, for the quick escape of the blood, upon which so much benefit depends; nor for the same reason allow of drawing a sufficient quantity at one time, to effect any good upon the spasmodic tendency or irritability of the vessels.

Local bleeding, in the plate vein for example, for a bruise in that region, does not enter exactly into our present view of the subject of blood-letting; because, as much service to the part affected may be generally derived from drawing off from the circulation at the neck vein, as spraying a vein immedi-
ately at the seat of the evil. Bleeding in the foot is the only exception we should make; unless the practice of incising the bars of the mouth when the animal will not take his corn, be another, or at least not of importance sufficient to be mentioned at all, even as an exception.

*The jugular vein* being sought for where it is largest and nearest the surface, this will be found upon pressing it with the finger, a hand’s breadth from the setting on of the head, a very little below the place where a branch comes from the lower jaw, and joins another from the upper part. The Frenchman instructs his *marechal* thus pithily on this topic, as on several others—"Do not bleed your horse in the head, but as near to it as possible." Its situation being thus found, take the fleam between the fore-finger and thumb of the left hand, and pressing gently upon the vein below with the other fingers, the vein will rise; then strike, with *stick* or *spring*, as the case may be, and continue the pressure until the proper quantity of blood is drawn off. If this latter necessary attendance is found inconvenient, the ligature may now be applied without danger, but with no additional advantage.

*Pinning up* the orifice is the final part of blood-letting that is frequently *overdone*; that is to say, too much of the skin is drawn up over the orifice of the vein, so that the blood will flow underneath the skin, which causes a swelling; and a fistulous tumour is the consequence, that is very trouble-
some to cure. When the quantity of blood taken has been small, leaving a redundancy in the system, this latter misfortune is likeliest to happen; but when the quantity taken has been large, and the horse rests quietly after it, the pinning up may be dispensed with, for the blood ceasing to flow of itself, the parts being brought together will adhere almost naturally, by holding the finger at the orifice for a few seconds. But when you must use a pin, be careful it does not prick the orifice of the vein.
ANALYTICAL INDEX

TO THE

MATTERS TREATED OF IN THIS VOLUME.

A.

Abscess, a disorder of the blood, 305; critical, 219, 314; deep seated, 317, 321. See Tumour.
Absorbents, what, 95, 124; their uses 148. See Absorption, Lacteals, Lymphatics.
Absorption, how performed, 126; its effects 129; great importance of, 142, 160; the cure of tumour, 320; fatal case of, 376; and escape, 377.
Adhesion, a disorder of birth, 5; extensive 6; called debility, 18, 196; how prevented, 87; consequent upon failure of the secretions, 74, 100; and on inflammation, ib.; uncertainty in life, 113; affects the legs' position, 32; of the lungs, 100, 103, 109, 200, 221; and the coat, 121; mediastinum, 218; of the great gut, 252; liver, 263; of the tendons, 482.
Age of horses, of great importance to buyers, 542; general appearance tells, 547; the teeth, manner of coming up, 549; marks on, 550; filing and bishoping, 548.
Aged, the, do not masticate aright, 269; retain chronic affections of the liver, 278.
Air, atmospheric and deleterious, compared, 119; benefits of good, 122, 176, 212, 321; evils of damp, 221.
Alteratives, the safest physic, 65, 125, 149, 151.
Alum wash for grease, 394.
Anatomy, not a disagreeable occupation, 12; method of conducting, 13—24, 449; of comparative, 134, note. See Examination.
Ankylosis, how occasioned, 76, 313, 391.
Anthelmintics, the natural, 410, 417.
Anticor, prevalent in France, 385; situation, 386; cause, ib. method of cure, 387.
Apoplexy, how incurred, 250, 256; what, 418. See Staggers.
Appetite, irregular, indicates diseased stomach, 410.
Arabs, practices of the, in cases of lameness, 456, 482.
Arteries, structure of, 125; hard vibration, 183; rigid, 194. See Blood-vessels.

Authors', the, apology, and views, 3. 10; researches, 8; reasons for publishing, v; method of study, vii.

Attenuants, thin the blood, 247; attenuating drench, 248.

B.

Back, shape of, how affecting health, 56—9; strain of, causes and symptoms, 478; remedies, 480.

Back-raking necessary, 149. 185. 255. 271. 420; manner of performing, 199.

Back-sinew, strain of, 481; its structure, ib.; remedies, 482—6.

Badcock, (Mr.) publishes White's compendium, viii. connection with J. Hinds, vii. ix.

Bandaging, mode of, for sore throat, 226; for strangles, 357; for abscess, 136; poll evil, 325. 336; a desirable accomplishment, 84.

Bark, a good tonic for well bred horses, 201. 238.

Bath, (the) recommended—warm, 205; how employed, ib.; the German, 206; in rabies, 435.

Bear baiting, experiment, 105.

Bee, (Jon.) condemns Clater's book, 2, note; recommends dissection, 151; and a treatise on hydrophobia, 437, note; the jointed shoe, 492.

Bile, how secreted, 148; its uses, 149; enters the intestines, 138, effects of superabundant and deficient, 14. 149. 276; appears by the dunging, 283.

Bishoping, what, and how to detect, 548.

Bladder, (the) its situation and uses, 155; physiology of 158; inflammation of its neck, 159. 270. 287. 290; palsy of, 160; errors concerning, 286; diseases of the, 290. See Urinary organs.

Bleeding, the best curative, or the worst, 83. 229; when needful, 179. 193. 226. 257—9. 279. 288. 387. 475. 480; the economy of, 179. 184. 211. 215. 291. 484; directions for, 558; improper, 211. 216. 279. 282.

Blister, liniment, 469; blistering recommended, 218. 316. 462. 469; its advantages, 279. 362.

Blind gut, its situation, and uses. See Cecum.

Blood horses, peculiarities of, 92-3; tender insides, 303.

Blood-vessels, what? 125; enter lungs, 101; and foot, 451; affect bodily health, 99. 114. 126. 316; circulation, physiology of, 114—130; extraneous substances found in, 125. 297. 304; how filtered of bile, 148; how of urea, 155; inflammation of, 183; quantity of, 559.

 Bloody urine, expected, 286; symptomatic, 296. 301.

Botts, symptoms of the, 411. See Worms.

Bowels, inflammation of, 197; lose their power, ib.; gangrene, 250. See Gut, Intestines.
Breeding, diseases of, 4; mistakes concerning, 61—64. 349. 457; of gelding, 169. See Colts.
Breaking down, how incurred, 486.
Bridges, (Jeremiah), his discoveries, correct, 452.
Broken heart, (a), no ideal disorder, 151.
Broken wind, how incurred, 105. 111. 237; indications of, 109.
Built, definition of, 3. 29; affects health, 5. 22. 27—30. 113.
Bunbury, (Sir T. C.) practice of running young horses, 457.
Byng's (Sir John) Tiresias colt dies, 487.

C.

Calomel applies itself to the liver, 290.
Calculus, or stone, resembles colic pains, 254. 300-302; causes of, 297; kinds of, 298. 305; cases of, 299. 301; treatment, fatal, 303.
Calken, strains the tendons, 494. See Shoe, frosting.
Camphorated spirits proper, 225.
Canine madness, causes of, 429. See Rabid animals.
Canker, what, 521; treatment of, 522; powder for, ib. prevention, 525.
Carry, low, how produced, 52. 59.
Castor oil recommended, 272 295; not always effectual, 186. 199; fit precursor of bleeding, 257.
Cataaract, cause of, 557.
Catarrh, (or a Cold), how incurred, 103. 111. 220; epidemic, 206; symptoms of, 222; remedy, 225; how resembling glanders, 371, 3. See Cough.
Cat-hammed, how affecting the tread, 43. 50. 52. 466.
Chamomile decoction, advised, 380.
Charge, (the), useless, exploded, 475.
Chest-founder, 538. See Consumption, Founder.
Circulation of the blood, its vastness, 297; effects of a slow, 303.
Carra, how accelerated, 560.
Clark, (Bracy), notice of his works, viii. 445; and shoes, 449. 492. 500. 508.
Cline's (Mr.) opinion regarding hereditary roarers, 241.
Clasters, an eligible application, 149. 211. 257. 259; laxative, 177. 253. 271. 420; soothing, 270. 283. 295; the sedative, 236. 264. 384. 396, 8; always clyster after back-raking, 200.
Coat, or skin, the outlet of disease, 167; of tender horses, 246; staring, accounted for, 5. 252. 409; amended, 201. 284.
Coat, shedding the, a cause of colds, 192. 243.
Coecum, the, its functions, 138; how injured, 139; a receptacle of calculous substances, 254. 298. 302.
Coffin-joint, error, 452. 461. 473; is strain of tendon, 481. 532; bone, what, 444, 5.
INDEX.

Cohesion, what? causes debility, 196. 255. See Adhesion.

Cold, (a), what? 110—112; causes and progress of, 206; mistreatment of, 109; effects of a general one, 174; or of a given organ, 177. See Catarrh, Roaring, Respiration.

Coleman, (Mr.), his opinions referred to, erroneous, 214. 447; his shoe patents, 500—4.

Colic, how brought on, 265; a source of inflammation, 252. 265; and reproductive of, 266; symptoms, 268; cure, 271; parallel symptoms of, 253. 4; when fatal, 274; pains mistaken for, 302; colic drenches, 273.

College, at Pancras, lectures discontinued, 2; propagate errors, 214.

Colts, mishapen in early life, 64; consequences of mounting too early, 457. 537; the contrary, 51.

Complication, what, 4. 222; what not, 17; case of, 155; real, 536.

Concretions, how formed, 139. 208. See Calculus.

Condition, horses in, suffer most, 176. 207. 215. 223. 252. 255. 261. 266. 355; test of condition, 188; out of, how affected, 191. 207. 256.

Conformation, what, 3; of legs, affects the tread, 33. 39. 44; and health, 4. 7. See Structure, Built.

Constipation, attends inflammation, 279. See Costiveness.

Constitution, change of, effected, 164. 560; a depraved, 372.

Consumption, term defined, 111; attends narrow chest, 60; and ill cured catarrh, 232. See Catarrh.

Contracted heels, how occasioned, 45. See Hoof, Foot.

Cooling decoction, what, 202; proper, 269. See Regimen.

Cordials, destructive, 258; induce colic, 267.

Corn, (the) how caused, 530; symptoms and mode of cure, 531.

Corn, when to be sodden or broken, 195. 201. 217. 226. 239. 261. 300; iron mill for, 301.

Cornish and Irish peasantry, large legs, 51.

Costiveness, an original disease, 183. 197; attends colic, 274; and molten grease, 261; and inflammation of the bowels, 255; and affections of the urinary organs, 267. 294.

Cough, defined, 224; causes of, 223; remedies varied, 229; no cough in glands, 371; constitutional, 221. 247; occasional, or plethoric, 244. 246—7; powders for, 248; chronic, what, 111 to 113. 242—244; how acquired, 221. 228. 233.

Coughing the horse, its effects, 102. 223.

Crib-biting, how brought on, 133; produces flatulence, 269.

Cruelty reproved, 53. 97. 139. 166.

Curb, cause of, 466; remedies, 467.

Cutting, how incurred, 36. 40.

D.

Debility, general notion of, too vague, 5. 17. 101. 111. 131. 191. 196. 221. 399; how induced, 267; affects colour of intestines, 145; fatal, 150. 202; brings on farcy, 376; the narrow affected, 390; owing to Adhesion, which see.
Diabetes, what, 291; symptoms and remedies, 293; generally mistreated, 295.
Diapente, prescribed, 190; a wrong notion, 202. 267.
Diaphragm, or, Midriff, physiology of, 85. 106; how disordered, 108; by Adhesion, which see.
Diaphoretic balls, 245. 234. 307. 395; ill effects of, 404.
Digestion, process of, 130—1; imperfect, its effects, 134. 189. 405; comparative, 170.
Digestive ointment, 328; second sort, 330; recommended, 221.
Diseases, (constitutional), predisposition thereto, 4. 118. 121. 150; how brought into activity, 124. 128. 131. 307; affect parts of the system, 166. 392; general principle of curing, x.
Disinfecting process recommended, 202. 208; details of, 374.
Disorders, the acquired or inflicted, 21; internal, 171; seats of, necessary to be known, 292; external, 305. See Disease.
Distemper, (the) 192. 206. See Epidemy.
Diuretics, often abused, 152; mode of operating, 156. 196. 235. 8.
Diuretic balls, 195. 231. 230; powders, 194. 394.
Docking, divides an artery, 123; cruelty of, unfashionable, 166.
Dog, (the), its cellular membrane filled, 105; system of life, 164. See Rabies.
Dropsy, how superinduced, 74.
Dudley’s cast iron shoes, 503. 514; objection to, 515.
Dung, (the), indicates state of health, 188. 196. 251. 255. 260; scanty in jaundice, 201; and deprived of colour, 282; how, 283; indicates worms, 411.
Dupuy, (M.), maintains the humoral pathology, 349.

E.
Ears, motions of, show disposition, 163; the barometer of inflammation, 194. 210. 269; folly of singeing, 169.
Eclipse, cast for his deformities, 26, note; vaulting manner, 38; not trained while a colt, 51; his proportions, ib.; large heart, 115.
Effusion, certain; but inscrutable, 79. 129; its effects, 160. 262; a cure, 210.
Embrocation, 239. 321. 322; for strains, 484. 5.
Epidemic fever, not infectious, 216; not dangerous, 213; how brought on, 192. 206. 222. 266; symptoms, 207. See Fevers.
Epiglottis, described, 102; with its glottis, ib.
Escharotics for fistulous tumours, 340; for sitfast, 363.
Evacuations, neglect of, its effects, 197. 251.
Examination of dead bodies, indispensable to Veterinary knowledge, 10, 11; its advantages, 16. 74. 141. 449; how available, 235. 390. 403; of the leg, 453.
Expectorant balls for cough, 229. drench, 231.
Eyes, important, indicate health and disease, 163; defluxions, or blear, 182. 223. 343. 357; symptomatic, 348; the healthy eye, 545; buck eyed, what? 556.
INDEX.

F.

Farcy and Poll-evil, connexion of, 319. 331; and with the glanders, 363. 378; resides in the blood, 377. 8; and affects the viscera, 378; yields to mercury, 392; cauterise the buds, 385.

Farriery, styles of teaching, various, 1. 7. 10, note.

Farriers, a kick at the old, 2. 83. 97. 166; and exhortations to the young ones, 11. 22. 84. 142. 299. 313. 449; mistakes in practice, 110. 113. 121. 131. 2. 135. 270. 1. 286—288. 295. 303. 364. 393. 409. See Veterinary.

Fat horses liable to disorders, 261. 265. 269. 282. 300. 304. See Condition.

Fatigue affects health, 26. 31.

Fayerman, (Dr.), case of rabies, successful, 435.

Feeding, and management of sick horses, 233. 250. 381; voracious, occasions broken wind, 237. 239; and cough, 244; and calculus, 299; and worms, 409. 411; manner of feeding, 60. 102; of old horses, 60; frequency of, 132; irregular, 138. 269. 281; bad, 266. 293. 305.

Fever of several kinds, traced, 182. 186; causes of, 182; crises of, 314; typhus, 176; or putrid, 202; symptoms, 203; rheumatic, 204; epidemic, 206. See Foot Fever.

Fever, (low), how superinduced, 94. 124. 138. 176. 191. 203. 251; similar to inflammation, (which see), 171; symptoms, 180. 187; differs from jaundice, 291.

Fever powders, 190. 295; fever drink, 190.

Firing, its effects, 462; undesirable, 364. 335. 436. 532. 534.

Fistula, what, 307; general treatment of, 322; resembles Tumour, which see; fistula in the withers, the horses most liable to, 43; origin of, 305; cause, 333; treatment, 335.

Flatulent colic desirable, 268. 9.

Flying Children, trained at five years old, 51.

Fomentations, how performed, 275. 336; proper, 345. 356. 481.

Food, proper, of the horse, 117. See Corn, Feeding, Hay.

Foot, the disorders arising from treading amiss, 7. 25—70; those of accident, 166, note; 451; of fore foot and hind, 490. 505. 517.

Foot, (the), necessity of studying, 339; section of, 443; internal structure, 444—450. 516; action of the, 453; fever of, 452. 472. 482. 490. 516; remedy, 518; diseases of the feet, constitutional, 516.

Forging, the effect of bad shape, and tiring, 50.

Founder, how brought on, 54; causes, 536; symptoms, 537; of the chest, 78; a complication, 535; treatment, 538.

Foxall, (Mr.), contriver of the warm bath, 205.

French method of studying the art, 12; and of cleansing sores, 337; practice in regard to lameness, 471. See Shoing.

Fretfulness accounted for, 98, note, 106.
INDEX.

Frush, or Thrush, what? 519; cause, ib.; and symptoms, 520; cure, ib.

Fumigation for the head, 359.

Functions of the organs of life, 72, 82; secret, 79, 129, 303. See Heart, Liver.

G.

Gall duct, choked up, causes jaundice, 280; physiology of, ib.

Gentian root to cleanse sores, 338.

Gillman on the bite of rabid animals, 436.

Girthing, (tight), unjustified, 53, 97.

Glands—of the solids, structure and uses of, 92; the salivary, 95, 364; offices of the various, 147, 360; enlargement of, 225, 315, 343.

Glanders, 305; connected with windpipe, 102; how engendered, 129, 147, 360, 358, 367; discussion as to the true and false, 363; causes of, 369; symptoms, 371; with true test, ib.; remedies and preventives, 373—6.

Goldfinch's, (Col.), jointed shoe, 492.

Goodwin, (Joseph), his praise of Clarke, 445; his shoeing, 495; objections answered, 499.

Grease, principle of, 152, 282; how incurred, 383; predisposition to, 319, 391, 440; remedies, 392—7.

Green food, a restorative, 217; denial of, 293. See Feeding.

Grooms, (the), reproved by White, 10; an altered set, 11.

Grooms' Oracle, (the), on Ventilation, 213.

Gruel of oatmeal, prescribed, 188, 195, 200, 212, 259; beneficial, 178, 217, 413.

Gut, (the), or colon, described, 140; great and small, suffer differently, 240. See Intestines.

Gutta serena, 558.

H.

Hand-rubbing beneficial, 205, 211, 215, 217; too much, relaxing, 467.

Hay, generates worms, 408; and some kinds carry them off, 410; causes staggers, 420.

H. C. valuable communications on rabies canina, in the Annals of Sporting, 437.

Head (the), its motions indicate pleasure, or pain, 52; large and small compared, 59; affected by foul stomach, 134, 137.

Heart, action of the, 106, 114, 117; its irritability, 123; size, 236.

Heat, the origin of most disorders, 3, 7, 171; of liver, &c. 276.

Hide-bound, appearance of the bowels in cases of, 77, 403; symptomatic, 131, 145, 150, 192, 210, 410; of the mesentery, 145; causes of, 403; cure, ib.; tonic remedy, 406; progress of, 411.
INDEX.

Hoof, shape and make of, 439; due elevation of, 44; brittle, 441. 489; and upright, 461; of preparing for the shoe, 505. See Foot, Tread.

Horn, of hoof, how formed, 339. 441. 448; process, 452; varies in elasticity, 489; contraction, 506; Horse (the dead) eulogy on his post-last services, 15; skeleton of, its uses, 20—24; speedy, suffer most in the lungs, 299; tender, 246. 268; horse milliners instructed, 226. 316. 325; precautions on purchasing, 543; French mode of buying, ib.; English notions of a good one, 545; trimming the heels, occasions grease, 389. 392; French horses heavy forehand, 386; greasy heels and white feet correspondent, 391; cause of distress, 404; does not engender rabies, 431; powers misapplied, 440.

Humours (the), definition of 305. 331; but being vitiated, originate all disease, 150. 152. 308-12; further proofs, 315. 331. 335; definitively, 343. 345. 348. 367. 561; occasion cough, 221. 352. those of the eye, 556. See Condition.

Hydrophobia, dog madness, cause of, 429; true definition of, see Rabies; list of writers on 436; mistakes concerning, 203; how disseminated, 204; incurable 427; water, a preventive, 429; not a true test of rabies, ib. 431, 432.

I and J.

Jaundice, cause of 151. 280; symptoms, &c. 231. See Yellows.

Inflammation, constant tendency to, 7. 103. 111. 135. 171; increased, 138; critical, 171; of the liver, 151; of the kidneys, 284; the prevalent disease of horses, 250; of intestines and stomach compared, 219; causes of, 252. 267; compared with colic, 253; and reproduced by it, 266; of various organs, 269, 270. See Bowels, Kidneys, Lungs.

Inoculation for strangles, 358; for glanders, 370, 376.

Intestines, the large first appear on dissection, 14; physiology of the, 135—145; functions, how lost, 139; pain, comparison of, 249. 303. See Inflammation.

Joints, stiff, 78. 313. See Anchylosis—rotten, how occasioned, 120. Irritating mixture, 327.

K.

Kidneys, structure of, 152-9; connected with the liver, 146. 154; torpor of, 153. 389; affected by rabies, 432; inflammation of, 284; causes, 285—288; affected, mistaken for colic, 269, 270; for the bladder, 284.

Knowledge of the functions of life indispensable to practitioners, 10. 12. 83. 114. 141; neglect of it, dishonest, 16. 84. Knuckle-over, a disorder of birth, 44.
INDEX.

L.

Lacteals, indicate state of health, 141; structure and uses of, 142; how offended, 145.
Lafosse’s opinion, 29. 302. 358; as to glanders, 364; on flat chest, 113; on spavin, 477; on shoeing, 506; manner of prescribing, xii.
Lameness, remarks on, 455-8. 554; from strains, 471; tests for ascertaining seat of, 457. 464. 474; rest indispensable for curing, 456.
Lamps, or Lampers, causes, 360; cure, 361.
Law (the) relating to glandered horses, 374.
Lawler (Denis) the horse-bather, his last feat, 476.
Lawrence (John) his imbecility and destructiveness, 2, note. (Richard) 213; controversy with White, 235; mistakes inflammation for colic, 266; denounces Taplin’s books, 2, note.
Leaping defined, and how performed, 52. 59.
Lee (James) the artist, his precision, 448. 550.
Leg and foot, structure of the, 438. 454; position of, explained mechanically, 30; stiffness of the, 287; disorders of the, 455.
Lentor, how occasioned, 93. 101. 150. See Fever, low.
Ligaments, their uses explained, 67; suspensory, of the neck, 68.
Liver, ulcered, tendency to, 124. 283; natural process, 122; its office, 124. 146—152; obstructed, 137. 149. 275; enlarged, 15. 151; inflammation of, 275.
Locked-jaw, principles of, 67; how incurred, 101; an effect, 421; case of, ib.; Wilkinson’s cases, 423.
Lotion, the cold, 345. 362.
Lungs (the) described, 99—113; appearance of, in disease, 103. 107. 111. 121; inflammation of the, 103. 111. 203; how detected, 103; cause of, 221; cured, 210; restoratives, 217; the size of affected, 236. See Respiration.
Lymphatics, structure of, 92, 93. 95; curative aid, 97. 126. 129.

M.

Making-up a horse, its effects, 268.
Madness (canine). See Rabid animals, Staggers, Staghounds.
Mallenders and Sallenders, treatment of, 470.
Mange, 401; ointments for, 402; cause of, 401-3.
Mares, draw their legs underneath, 31; adaptation of, to horse, 61; bladder of, 159; liable to affections of the kidneys, 284. See Breeding.
Medicine, discrimination in the employment of, 176. 183. 191. 195. 202. 238. 271. 355. 393. 415; very few required, x.
INDEX.

Megrims (the), what? 419; remedies, 420.
Membrane—covering bones, its uses, 65. 69; colour and affections, 70; secrete aqueous particles, 76; structure and uses, 87; cellular, experiments on, 88; mucous, secretion of, 103.
Memory, extent of, in the horse, 97, 98.
Mercury, when desirable, 177. 397-415; a specific in farcy, 382; unavailing in glanders, 376.
Mercurial balls, 383, 384. 413; regimen during a course, 384. 414;—wash, 394.
Midriff, physiology of, 106—109. See Diaphragm.
Millers' horses incur the stone, 299.
Mineral acids, recommended in Rabies, 435.
Molten grease, described, 261; its causes traced, 262; treatment of, 264; an effort of nature, 267; relics, 293.
Moorcroft, (Mr.) his shoe, how failing, 498; on paring, 506.
Moulting seasons, effects of, 193. 222.
Mouth, physiology of, and mode of feeding, 60. 102; denotes age, 553; dry, indication of, 188; hot, 187.
Muscle, structure and functions of, 90—93.
Musgrave's (Sir T.) Walton colt, breaks down, 487, note.

N.
Nail driving, modern mode of, 496. 508. 512.
Navicular bone, 444; diseases so termed incorrect, 43. See Coffin.
Nerves, physiology of the, 97. 427.
Nimrod, the writer, confirms the doctrine of the tread, 9; on the bladder, 490.
Nose, running of, symptom favourable, 216. 224; of simple cold, 223.

O.
Ointment for fistula, 338; for sitfast, 363; for anticor, 337.
Operation for poll-evil, 320. 324; for abscess, 314. 317; precautions, 315. 320. 322; on the wen, 307; fistula, 336; for strangles, 354. 357.8; for lampas, 361; for sitfast, 362; for glanders, 364; for anticor, 387; for eruptions, 470; for grease, 307; for quittor, 460.
Opium, as a sedative, 238. 306; tends to constipate, 273. 424. 425.
Organs of life, their functions, 71; traced and noted, 20; sympathy of, 169; the minor, 71. 82. See each by name.
Ormskirk medicine, unworthy of reliance, 436.
Osmer's shoe retains its character, 499.
Overreach, how incurred, 50.

P.
Pace, how obstructed, 3. 35. 67; how promoted, 39. 51. 65. See Progression.
INDEX.

Pain, how communicated, 292; colic, mistaken, 301. Pampered horses liable to gripes, 268. See Fat. Pasterns, of the upright and short, 45; sloping, 43. Patents for shoes not tenable, 498-9; specifications, 492. 502-5. Pearson (Dr.) rebukes the professor, 447. Pegged foot, how detected, 556. Perspiration, the sensible, and the insensible, necessary to health, 73; one of the means of cure, 77. 245; experiment on, 79. Phenomena, the trotting mare, her powers, 38. Physic, how turned aside from its purpose, 81; not always a remedy, 84. 135; ill-adapted to its purposes, 131. 393; when necessary, 177. 347. 361. See Alterative Purgatives. Pinckard's cases of hydrophobia, 436. Pledgets for fistula, 340. Pleura, physiology of the, 100; its doubling, or mediastinum, ever disordered, 218. Pleurisy, an uncertain disease, 218. Poisonous vapours, effects of, 120; oil a good preventive, ib.; slow, how operating, 125. 131. 134. Poll-evil, its seat exhibited, 69; a disease of the system, 305; causes, 318; symptoms and cure, 320; second method, 322. Pommice foot, the effect of age and bad form, 44. Poultice, efficacy of, 225. 470; mode of applying, 226. 356; drawing, 316. 324; of bread, 340; of turnips, 397. Pressure (frog), Mr. Coleman's contrivances to obtain, 502; the right degree of, 505. Progression, principles of, 30. 34. 52. 59. 66. 555. Pulmonary arteries, what, 111. 119. 122; affections, 222. Pulse, theory of the, 123; practice of feeling, 142. 224. 254; how accelerated, 127. 198; how occasioned, 116; tells when to bleed, 177. 215; and to rowel, 218; low and slow, 193. 260. 281. 336; variable, denotes relapse, 279. 422; quick and sharp, 291. 293; observations on the, as a barometer, 197; register of, in health, 130. Purchasers of horses, precautions to be observed by, 542. Purgatives, the most obvious curative, 84. 282; an over dose, its effects, 136; dangerous, 186. 199. 246. 255. 260. 267; necessary, 184. 211. Purging ball, 185. 244-5. 289. 361. 395. 414. 434; clyster, 185. Putrid fever—cause, symptoms, and remedies, 202-4.

Q.
Quittor, how caused, originally, 339; general treatment of, 322. 340. 459.

R.
Rabid animals, manner of, 430. 433.
INDEX.

Rabies, how incurred, 204. 429; symptoms, 431; progress of, 432; remedies, 433. References, (the) explained, 24; an instructive exercise, viii.

Regimen (the cooling), efficacy of, 110. 113. 122. 125. 178. 201. 232. 290. 321. 335; the restorative, 193-5. 237. 282. Register (a) of dissections, model of, 13. 17—20; of the pulse, 180. Relapse, the danger of, in various instances, 189. 201. 226. 232. 240. 260. 280. 485. Respiration, organs of, described, 99; act of, what, 98. 102; great importance of, 99; experiments on, 104-5. 108; diseases of, 110. Rest, the universal remedy for lameness, 518. Rheumatism, a disease of horses, 204; hot bath for, 205; its seat demonstrated, 70. Ring-bone occasioned by bad form, 45. 461; incurable, 462. Roach back, a defect, its consequences, 54. 59. Roaring, how incurred, 242; how tested, 139. 247; not here- ditary, 241; theory of, 234, 241. See Broken wind. Rotch's jointed shoe, 492. Running (a), at the nose a system of farcy, 378; not always glanders, 369; at the eyes, 364, note. Roweling and blistering compared, 218; not always proper, 279; a superficial inflammation, 316.

S.

Saddle-galls, nature and treatment, 361. Sallenders, what, 470; and treatment, ib. Sand-crack, cause and symptoms, 526; cure, 527. Saturnine lotion, 334. Scalding mixtures for poll-evil and fistula, 328, 329. 337. Scouring, occasioned by bile, 281; never dark coloured, 283. Scrophula, not a disease of horses, 350. Secretions (the), what, and how performed, 72—79. 81. 103. 126. 155; uses of the general one, 73. 131; kinds, 76. 124. 133. 146. 261; nice distinctions unnecessary, 77; performed by glands, 94; defective, its tendency, 100. 103. 131. 149. 293; superabundant, expelled, 262. 267; of horn, 446. Sedative balls, 274; proper for travellers, ib. Setons, when proper, 219. 326. 336; See Rowel. Sewel (Mr.) pretends to cure the glanders, 376; and obtains a bonus for his pains, ib. Shivering, the presage of death, 274. Shoe (the), an iron defence, 488. 499; the form, 489. 493. 495; weight, 506; spring, 494; the improved, 496; of frosting, 494; must be firm, 489. 509; hardening the, 496; the jointed, 492. 498. 500 to 504; Clark's, 500; Colman's, 502; Goldfinch's, 501; Rotch's, 500; the grooved, 497; web, 493; cast iron, 503. 514.
INDEX.

Shoeing smith, (the) his duty, 441. 488—492; a remedy for false tread, 41. 50. 496; causes splents, 469; and bone spavin, 465; of preparing the hoof, 489. 505, 506, 507; for diseased feet, 498. 513; of fullering, 493. 497; punching, 494. 497. 502. 510; nailing, 496. 498; driving, 512; clenching and rivetting, 513; French method, 445. 492.

Shoulder, conformation of the, 40. 308; how set on, 333; strain of, 473; how ascertained, 474. shoulder shook, how effected, 78. 525.

S Pitts, what? 361; treatment of, 362.

Skeleton (the) of a horse, described, 22—24; peculiarity of, 318.

Skittish horses, posture of, 32; how induced, 169.

Sole, danger of paring too much, .

Spasmotic affections of the intestines, 265; how treated, 425; appearance of the spinal canal, 427.

Spavin, various, 463; the bog, or blood, ib.; bone spavin, 458. 464.

Spavin (bone) and splent, how operating, 70.

Sprain, how differing from strain, 472-3.

Splents, cause of, 467; remedy for, 468.

Sponge boot, the, recommended, 540.

Stable air, affects the lungs, 93. 213; and the blood, 120. 212. 176. 379; how arising, 157. close, renders a horse tender, 267; hot, affects the kidneys, 285; cold, causes grease, 380. 392.; infected, to cleanse, 375; the loose, restorative, 98, note, 475. 485.

Staggers, cause of, 134. 196. 204. 418; remedy, 420.

Stag hounds, the king's, destroyed for rabies, 435.

Stalking, how affected by retention, 159. See Urine.

St. Bel, mistaken regarding the cure for glands, 376.

Stallions, (of) choice, service, and keep, 61. 456; too much excitement destructive, 250. 267. 418; die in covering, 62. 268.

Steaming the head, good for catarrh, 225; for strangles, 357.

Stifle, strain of the, 477; remedy, 478.

Stimulants, harmful, 271. 286. 302. 409. 418.

Stimulating liniment, 356.

Stomach, how diseased, 108-9; physiology of the, 131-5; large, undesirable, 132; inflammation of the, 249.

Stone, cases of, 154. 299; and other calculus, 297; how concreted, 298.

Stopping recommended, 518; the cooling, 528.

Strains, what? 457. 471; of the back sinew, i.e. of coffin joint, 481. 532; of ligaments, 68; of shoulder, 473; treatment, 475; whirl-bone, 477; stifle, ib.; the back, 478; cause of, 479; treatment, 460; violent ones, 463.

Strain of coffin joint, the principle objected to, 43.

Strangles (the), what? 351; inoculation for, ib. 356; bastard strangles, 359; strangles of the gullet, 358.

Stone, how formed, 160; case of, 155, note. See Concretion.

Stringhalt, how incurred, 33; motion of, 478.

Structure, how affecting pace, and health, 3. 25. 27. 36. 39. 61. 64. 433; valvular, 117. 133; internal, 5.
INDEX.

Study, utility of, 4; method of, 10, 22; the French, 11, note. 442.
Surbating, an old term for founder, 535.
Surfeit and mange, cause of, 398; cure, 400—402; wash for, 400.
Surr, (John) on Hydrophobia, 437; an aspiration to his memory, ib. note.
System, (the), definition, 162; depraved, affects the foot, 48. 67; valvular structure pervades the whole, 117; it works off disease, 170.
Sweating restores the aqueous secretion, 73. 79; its appearance varies, 76. 80; ball, 211. See Diaphoretics.
Swimming the horse for shoulder strain, 476.
Taplin, (W.) his books dangerous, 2, note.
Teeth, denote the age, 548; by marks, 550; by shape, 554.
Tendon, texture and uses, 91. 453; supplies the place of muscle, 92-3.
Terms used in describing a horse, 543.
Thoroughpin, what? 462; remedy, 463.
Throat, (sore) symptoms, 224; remedy for, 226.
Thrush, 519.—See Frush.
Tongue, indicates state of health, 168.
Tonics, requisite, after disorders, 189. 238. 426; all bitters are so, 417; tonic balls, 201. 238. 294-5. 406.
Tooth ache, a disorder of the horse, 81.
Tread (the), how affected, 7. 36. 39. 41. 68; the curved, 43. 49. 53; depends on muscular action, 92; various kinds, 438.
Trotting—powers discovered, 27; how performed, 38; imperfectly, 59.
Tubercular diseases, 353. 399; internal, 145. 252. 400. 403. 407; catastrophe attendant on, 406.—See Tumour.
Tumour and Abscess, the nature of, 305. 347; the horse very liable to, 311; how produced, 306; how absorbed, 282. 312. 322. 351; the critical, 219. 306. 314. 353; external, 306. 347; internal, 145. 283. 310; the single and the diffused, 380; indolent, 307. 346.
Typhus fever, causes and symptoms, 202; communicable, ib.; appearance, on dissection, 203.

U and V.
Valvular structure, various, 117. 133. 137.
Veins (the), take their rise, 93; structure of, 127—9.—See Blood Vessels; veins and arteries, their co-construction, 127.
Veterinary instructors, their style of teaching the art, 2. 118; self contradiction of one, 404; argumentative, 304; their perplexities noticed, 5. 101. 118. 125. 137. 142. 145. 161. 214. 218. 252. 266. 286. 302. 332. 374. 384. 404. 406. 408. 414. 445. 447.—See Farriers, and see each by Name.
Vives (the) what, 342; resembles strangles, 343; cure for, 344; by suppuration, 346; false vives, ib.
 INDEX.

Urine, the principle of, 157. 159. 196; colour indicative of disease, 183. 195. 255. 263. 270. 294; and of jaundice, 282; of bloody, 282. 290. 296; urine balls, often unnecessary, 393; their suspension ruinous, ib.; turbid, 289; bloody, causes and treatment of, 285. 301; suppression of, 287. 432; incontinence of, 290. 295; retention of, 290.

Urinary passages (the), an eligible means of cure, 152; the organs described, 158; employed in secretion, 155; diseases of the, 292; affect the hind feet, 499; mistaken for colic, 269; general error concerning, 490.

W.

Walk (the), governs other paces, 29. 32.
Walk of hoof, formerly termed the Coffin, 444; is alone to bear on the shoe, 505.
Wallis, (Thomas) noticed the jointed shoe, in 1766, 492.
Warbles, general treatment of, 362.
Wash for the frush, 591.
Water, frequency of, necessary to health, 239. 243; rejection of, no test of rabies, 429; turbid and stoney, 298.
Wen, 307.—See Tumour, indolent.
Whirlbone, sprain of the, 477; remedies, ib.
White, (James) vague descriptions, 118. 447; of worms, 138; suppression of urine, 161; on the humours, 308; a plain writer, 3; attacks the grooms, 10; and R. Lawrence, 235; mistakes kind of regimen, 414; mode of fomenting, 481; his character of J. Lawrence's books, 2, note. his compendium mutilated, viii.
Wilkinson, (Mr.) his treatment of locked-jaw, 423.
Windpipe, construction of, 101; diseases of, 102.
Wind, broken, of several kinds, 233—237.
Wind, theory of, 101. 105; trying it, 102. 247; touched in the, 111.—See Respiration.
Windgall, causes of, 462; cure, ib.
Worms, a secondary consideration, 249; difficulty of ascertaining, 408; errors of writers concerning, 5. 101. 121. 137. 145. 252. 404. 409; cause, 408; symptoms, 410; cure, 412.

Y.

Yellows (the), cause of, 275; symptoms, same as inflammation of the liver, ib.; yellowness a symptom of fever, 292.

CONVERSATIONS ON CONDITIONING.

Just Published, in one Volume, price 7s.,
with an elegant Frontispiece,

THE GROOMS' ORACLE, and Pocket Stable Directory, in which the management of Horses generally, as to Health, Dieting, and Exercise is considered, in a series of familiar Dialogues between Two Grooms engaged in Training Horses to their work. With Notes, and an Appendix; including extracts from the Receipt Book of

JOHN HINDS, V.S.

AUTHOR OF VETERINARY SURGERY, &c.

Published by SHERWOOD & CO.; HURST & CO.; and WHITTAKER & CO.

OPINIONS OF THE JUDGES.

"** Where commendation is general and uncontradicted, no more need be said, in ordinary cases; but vanity, if not interest and the consciousness of having laboured to a good purpose, superinduces the subsequent quotations from contemporary writers.

The Sporting Magazine for May, 1829, expresses its surprise that hitherto "no Stable Guide, addressed to the capacity of servants, should have issued from the press. All the old books of farriery from their stiffness, failed to instruct as they ought; but in this volume, the matters treated of, independent of the manner in which it is executed, is much to be commended. We nowhere discern a wish on the part of the Authors to display fine learning; but on the contrary, they render topics of the most difficult nature perfectly intelligible to the meanest capacities. As to the points upon which they converse, we discover none omitted that could be desirable to the practical horse-keeper or owner,—the most common-place that may be known to every trainer of eminence, in part or in the whole, being brought forth in a pleasing and truly instructive manner for the benefit of the less-expert and junior persons. But we must quit The Oracle, by recommending it to the notice of those for whom it was specially compiled." Pages 34—6.

"Mr. J. Hinds' Grooms' Oracle not only comprehends every kind of information relating to the diseases of a horse, but gives ample and admirable directions how that noble animal should be treated so as to obviate disease in every variety of service in which it may be employed." Vide Taunton Courier, April 8, 1829.

"The matter taught, we are fain to believe, is of the utmost importance to the well-being of horses of every description, and of the higher bred cattle in particular; the object of the speakers being to talk of training horses into fit condition for getting through their work
Works by the same Author.

in style—Whether that be of the Turf, the Chase, or the Road. As usual in works of this nature, amidst much that is quite new information, there is a good deal of intelligence, that is known to all Training Grooms, as 1st. The mode of keeping down flesh whilst keeping up the stamina; 2nd. Of putting pace into the horse; 3d. Of improving his stretch and form of going, as well as sustaining his lastling qualities." Vide Age, March 22.

The Weekly Dispatch, sporting newspaper, goes on with its observations on the state of the Veterinary Art, that "the immense advantages of all post mortem examinations, is evident to all but the meanest capacity, and was strenuously insisted upon in the Authors' former volume, as it is again in this Grooms' Oracle in more familiar terms. If the practice of Veterinary Medicine and Surgery is thus in a fair way of being disclosed to vulgar eyes, and laid open to the comprehension of ordinary minds, no less so is the Art of Training horses into condition for every species of work here placed in a more just and rational light than we have hitherto been in the habit of hearing and seeing the subject treated of. By the way, we are very much mistaken if the grooms' employers may not derive as much pleasure and profit from the perusal of these Conversations as the class of persons for whose use the volume appears to have been ostensibly designed."

In the Press, from the same pen, and same size,

A NEW AND COMPLETE

DICTIONARY OF THE VETERINARY ART;

In which the Terms employed by various Writers, and the respective orders of practitioners are explained, under their popular and scientific acceptations: as are, also, the usages, remedies, prescriptions, varied regimen, applications (topical and potential), bandagings, operations, Materia Medica, &c. in the modern practice of Farriery and Horse Keeping: compiled with a view to practical results only, and their employment in the cure or mitigation of diseases in horses, dogs, cattle, sheep, and swine.

The whole offering the means of ready reference to every topic connected with brute-animal economy in health and disease, in accidents, infections, work, and management; as to comforts, privation, feeding, reproduction, and culture; but divested of controversy, doubts and jarring of opinions, and offering only the best and readiest modes of meeting derangements of the animal system, and amending defects, of curing disorders, and avoiding error.
